VRE	Virginia Railway Express
WUS	Washington Union Station

1 **Appendix S2** presents more detailed descriptions of the major components and features of Alternative F to
2 supplement the summary in **Chapter 3, Section 3.3, *Description of Alternative F***.

S.1 Tracks and Platforms/Rail Support Function

3 Alternative F would replace the existing tracks with 19 new tracks: 12 stub-end tracks on the west side and
4 seven run-through tracks on the east side. There would be 10 new platforms. The Central Concourse (see
5 **Section S.3, *Concourses and Retail***, below) would separate the stub-end tracks and platforms from the run-
6 through tracks and platforms. The stub-end platforms would be at the same elevation as Concourse A,¹
7 allowing direct access for passengers coming in through the southern end of the station. The run-through
8 platforms would be at a lower elevation. Passengers would reach them via vertical circulation elements (such
9 as stairs, escalators, or elevators). Vertical circulation elements in the middle of all the platforms would bring
10 passengers down to the H Street Concourse. The tracks and platforms would be open on both the east and
11 west sides of the rail terminal to let light and air in.

12 The run-through tracks pass through the First Street Tunnel underneath the east side of the historic station
13 building as they converge toward the two-track portion of the tunnel via Interlocking A. Construction of the
14 new tracks and platforms would require reconfiguring Interlocking A and realigning the tracks. To accomplish
15 this, 18 of the 28 building-supporting columns that currently extend from the track bed to the floor of the
16 Retail and Ticketing Concourse would have to be removed.

17 From north to south, the existing columns are arrayed in one east-west line of three columns (Column Line
18 A.1) and five east-west lines of five columns (Column Lines B through F). The track bed in the portion of the
19 tunnel between Columns Lines A.1 through D rests on a structure—the Subbasement Structure—that spans a
20 lower-level space—the Subbasement Area—presently housing electrical substations and utility conduits (see
21 **Figure S-1**).²

¹ Concourse A generally is encompassed within the train hall, adjacent to, but distinct from, the historic Retail and Ticketing Concourse.

² The condition of the Subbasement Structure has deteriorated over time. It is slated for replacement as part of a separate and independent project that would be completed before work on the tracks and platforms starts.

Figure S-1. Model Showing Subbasement and Columns to be Removed

Source: Amtrak. May 10, 2019. *Project Definition Report. Washington Union Station Subbasement Structural Replacement Project.*

22 Column removal would require installing temporary shoring towers and foundations³; potentially
23 demolishing the Retail and Ticketing Concourse floor as well as the retail shops above the tunnel; potentially
24 removing the historic terracotta and concrete floor structure and installing new transfer girders; removing
25 three of the five columns in Column Lines B through F; strengthening some of the remaining ten columns;
26 reconstructing crash walls between the tracks; and replacing the three columns of Column Line A.1 with two
27 new columns. Column Line A.1 supports the barrel vault roof of the Retail and Ticketing Concourse and the
28 heaviest loads. Like the existing columns, the two new columns in Line A.1 would rest on the northern
29 abutment of the Subbasement Structure.

30 The construction of temporary shoring towers on Column Lines E and F, which are not above the
31 Subbasement Area, would potentially require the installation of foundations. Column removal would also
32 likely require replacing a portion of the First Street tunnel's existing east wall. In its current condition, this
33 brick masonry wall may not be able to adequately support future transferred loads. If this is confirmed, it
34 would likely be reconstructed as a concrete wall (like the existing west tunnel wall) or steel support system
35 with adequate load-bearing capacity.

36 Alternative F would place rail support spaces primarily north of the H Street Concourse, on the lower
37 concourse level and just below existing street grade. Rail support would have access to the tracks and
38 platforms via dedicated service elevators without having to cross any tracks and with minimal disruption to
39 passengers. This would also support more efficient train servicing and, therefore, shorter dwell times.⁴

³ Depending on how design progresses, some foundations may be left permanently in place.

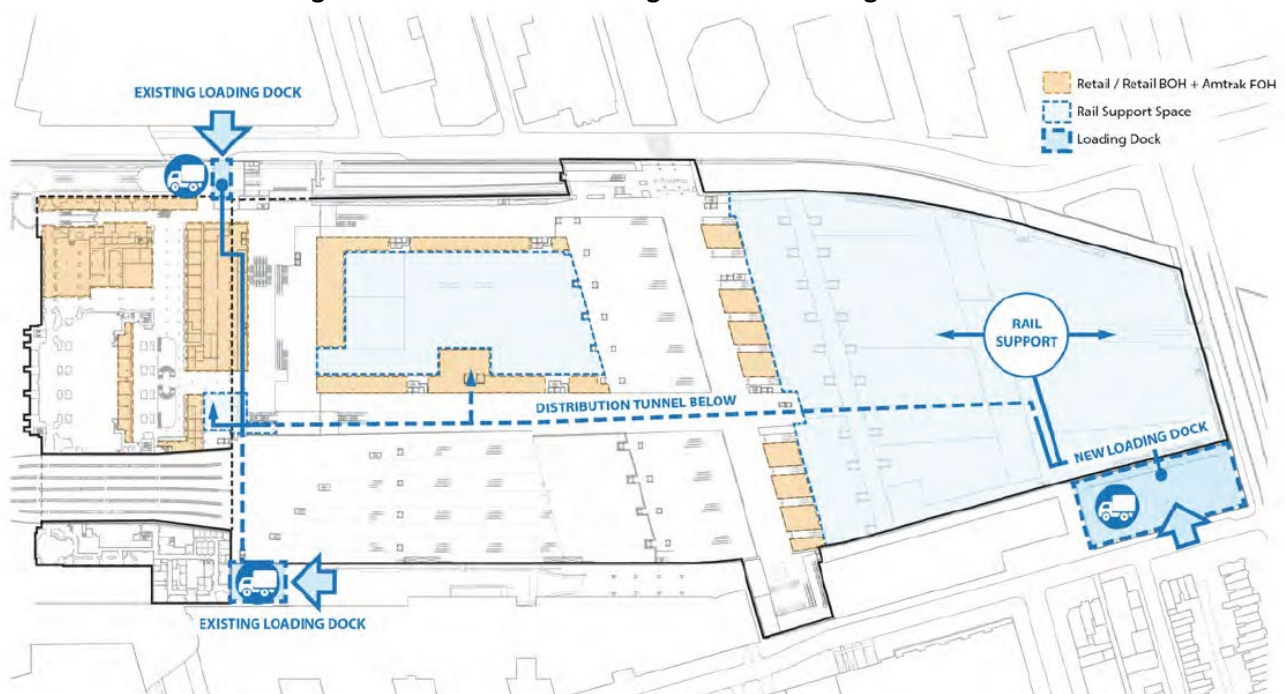

⁴ Dwell time is the time that trains sit at platforms during loading and unloading operations.

40 Amtrak would use the dedicated service elevators for train servicing, baggage movement to trains, and
41 commissary support.

S.2 Loading

42 In Alternative F, the two existing Washington Union Station (WUS) loading docks would continue to support
43 the unloading and distribution of goods at the station. On First Street NE, in the section that would become
44 one-way north (See **Section S.8, Pedestrian and Bicycle Access**), a pull-out lane by the U.S Post Office Building
45 across the street from the First Street loading dock would facilitate turns into the dock. Additionally, a new
46 loading dock would be provided on Second Street NE, adjacent to the Railway Express Agency (REA) building
47 (see **Figure S-2**).⁵ Users of the new loading dock, which would have 6 berths and 2 trash compactors, may
48 include new retail and Amtrak’s back of house activities.⁶ A new service building would be constructed above
49 the new loading dock. The height of this structure would approximately align with the cornice line of the REA
50 Building and would occupy the area of the current substation (which would be removed under a separate
51 and independent project).

Figure S-2. Location of Existing and New Loading Facilities

⁵ The Amtrak-owned REA Building is located just west of Second Street NE and north of the H Street Bridge.

⁶ “Back of house activities” include the servicing of trains, the storage of equipment for maintenance and operations, and the provision of operational space for staff.

S.3 Concourses and Retail

52 Several new concourses would facilitate public access to, and circulation through, WUS. The concourses
53 would connect the various transportation modes serving the station, including the train platforms, the bus
54 facility, the Metrorail station, and the DC Streetcar. Additionally, the concourses would offer various services
55 and amenities, such as information, ticketing, and baggage services. Waiting areas would provide secure and
56 organized access to the platforms. Retail would be available for passengers and visitors circulating through
57 the station. **Figure S-3** and **Figure S-4** show the proposed concourses. Brief descriptions follow:

- 58 ■ **Concourse A:** This east-west concourse, which would replace the Claytor Concourse and be
59 integrated with the train hall, would connect directly to the existing Retail and Ticketing
60 Concourse and the stub-end platforms as well as to the Metrorail station. The concourse would
61 have room for passenger amenities, including waiting areas and retail. It would also provide
62 access to the other concourses via vertical circulation elements.
- 63 ■ **Central Concourse:** This north-south concourse would connect Concourse A and the train hall to
64 the H Street Concourse. It would have new retail uses for passengers and visitors.
- 65 ■ **H Street Concourse:** This east-west concourse would run below H Street NE and provide access
66 to the train platforms. Passenger amenities and services would include information, police
67 station, ticketing, baggage services, and retail. New waiting areas would facilitate movements up
68 the escalators or elevators connecting to the platforms. The concourse would also connect the
69 neighborhoods east and west of WUS with entrances at First Street NE and Second Street NE.
70 Vertical circulation elements would bring people up to H Street NE, providing a transfer point to
71 the DC Streetcar and other transit on H Street.
- 72 ■ **First Street Concourse:** This north-south concourse would run parallel to First Street NE and
73 connect the H Street Concourse to Concourse A and the Metrorail station. Retail would be
74 available along the concourse.

Figure S-3. New Concourses in Alternative F – Upper Level

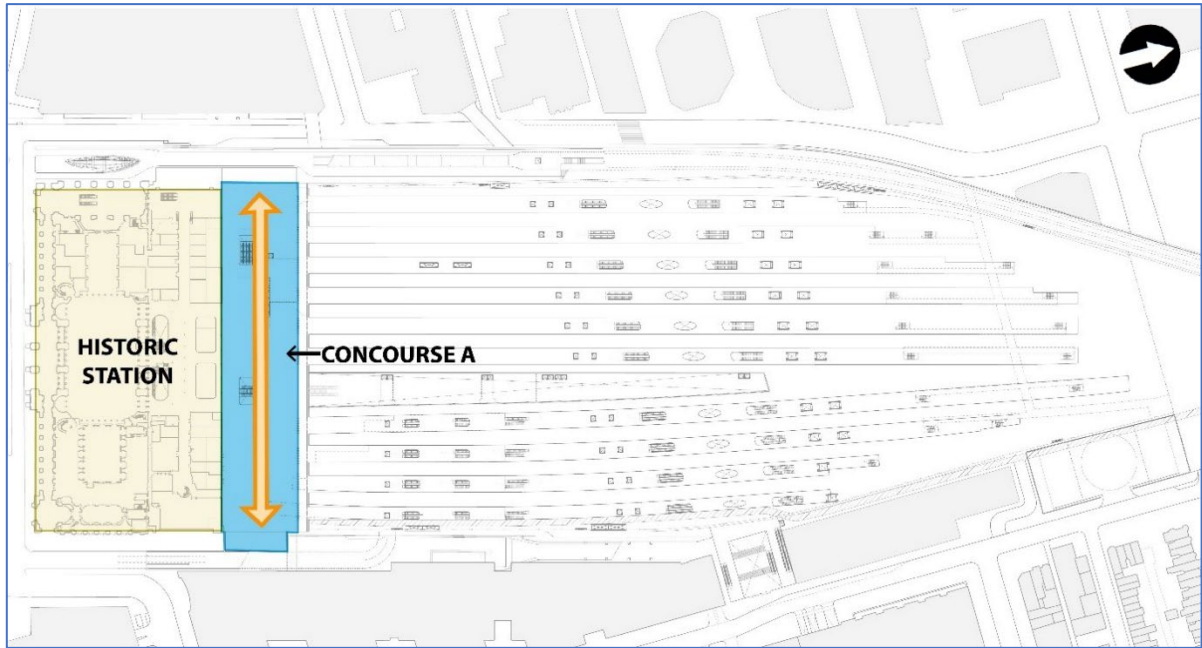

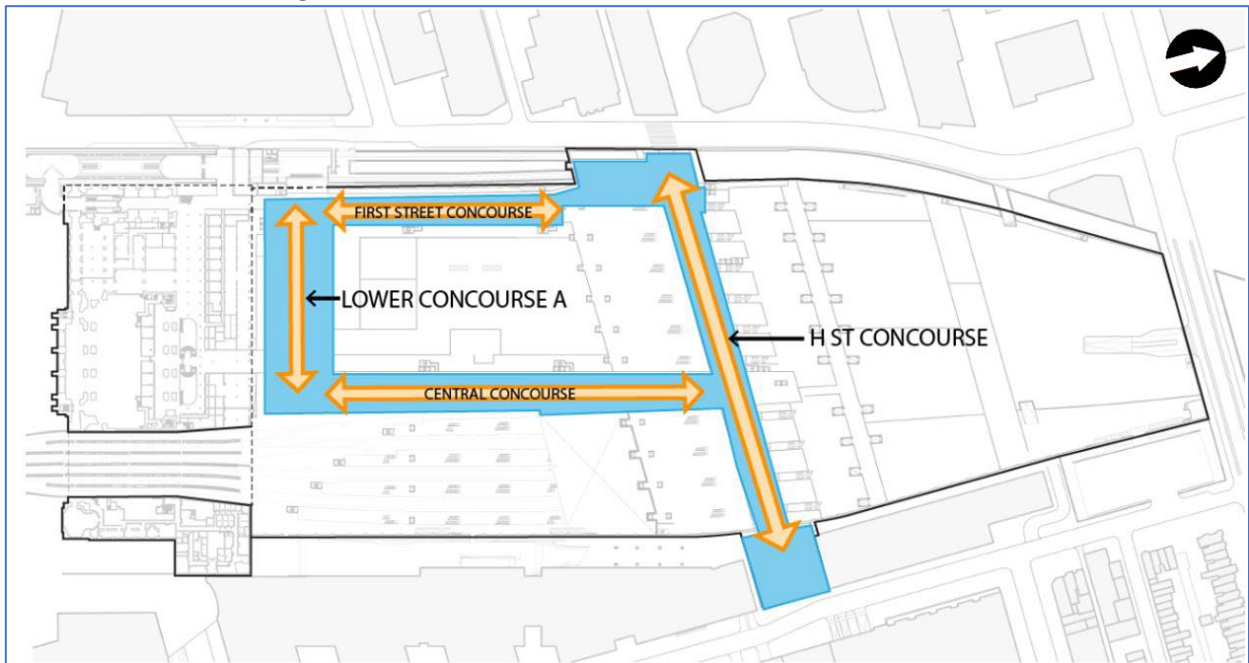

Figure S-4. New Concourses in Alternative F – Lower Level

S.4 Train Hall

75 In Alternative F, an east-west train hall would encompass Concourse A and part of the southern end of the
76 tracks and platforms, including the area currently occupied by the Claytor Concourse. To the south, it would

77 open onto the historic station building. A vertical glazed wall would separate the platforms from the train
78 hall, which would be sealed and ventilated. Although the design of the train hall is in development, it is
79 anticipated that it would not duplicate the form, material, or architectural features of the historic station to
80 avoid compromising or competing with it. **Figure S-5** shows a conceptual rendering of the train hall’s interior.

81 The train hall would be approximately 55 feet above H Street NE, and about 40 feet lower than the vaulted
82 roof of the historic station. As illustrated in **Figure S-5**, the train hall would have three levels of passenger
83 circulation: the ground level (Concourse A) would connect directly to the historic station building to the south
84 and to the stub-end track platforms to the north. This level would provide access to the lower concourses
85 and the run-through tracks and platforms via vertical circulation elements. Overhead, the lower mezzanine
86 level would provide access to, and passenger facilities for, the bus facility. Finally, above the lower
87 mezzanine, the upper mezzanine level would open onto the deck and the deck-level pick-up and drop-off
88 area. Entrances to the train hall would be located on its east and west sides.

Figure S-5. Conceptual Rendering of Train Hall Interior in Alternative F (Looking Northwest)

S.5 H Street Bridge Intersections and Deck-Level Circulation

89 Alternative F deck-level circulation patterns are illustrated in **Figure S-6**.⁷ Two new intersections (west and
90 east) would be established to connect the H Street Bridge to the deck via two new roads WUS-traffic would
91 use:⁸

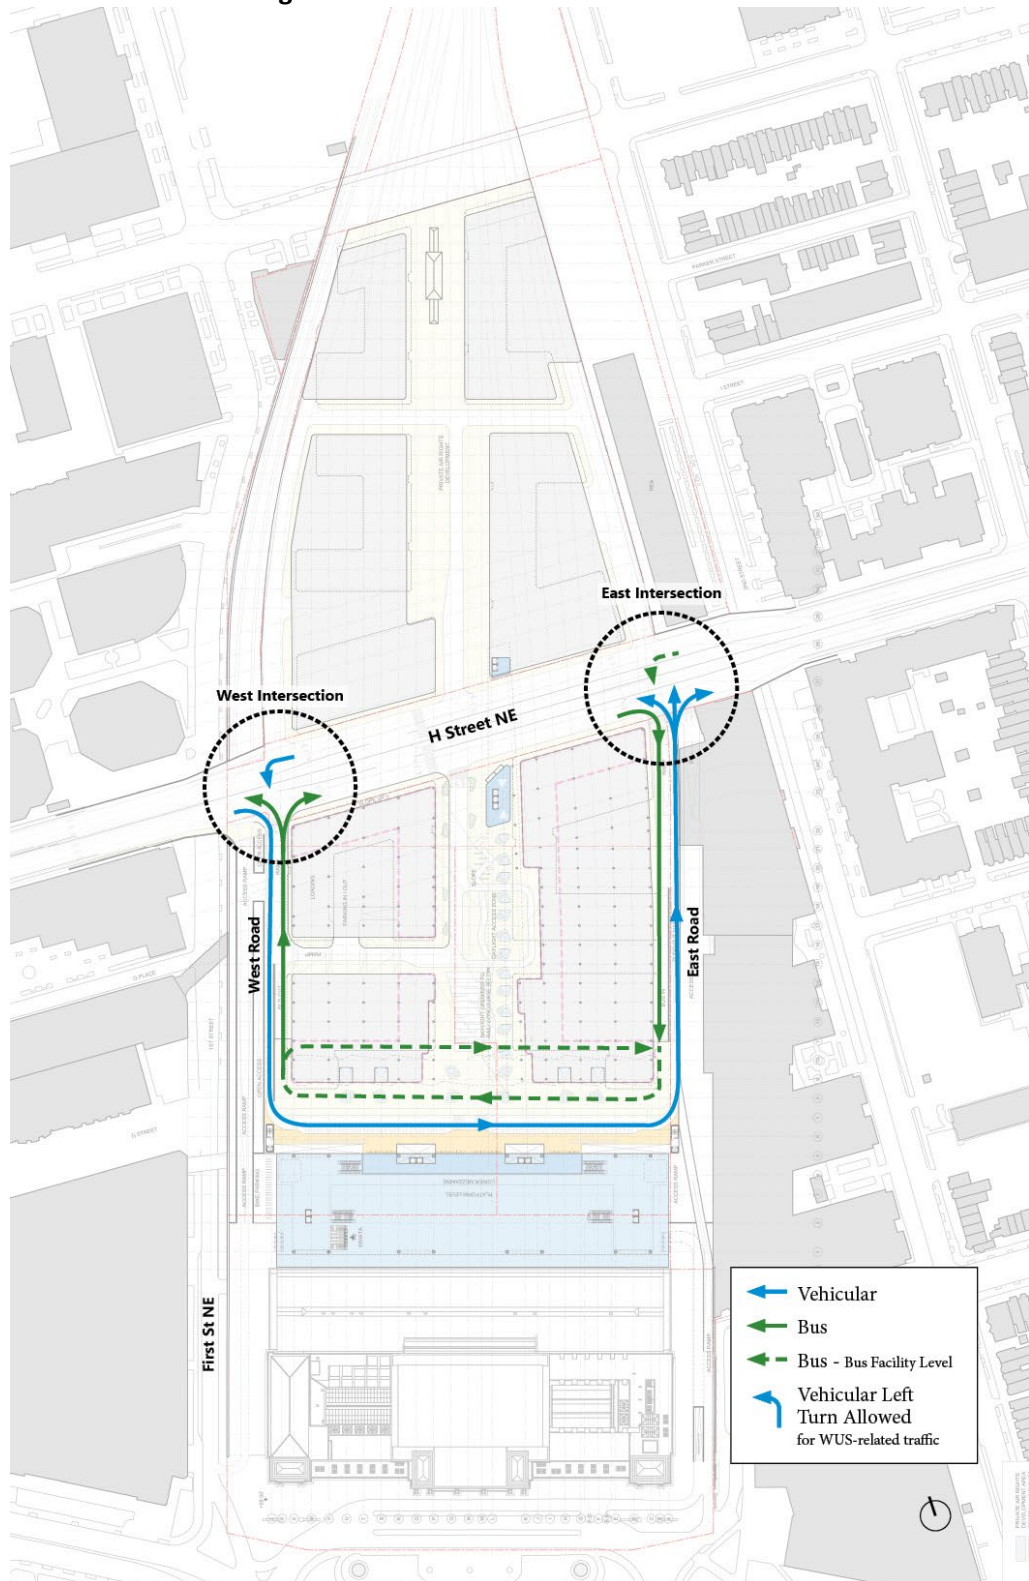

- 92 ■ **West Intersection:** The new west intersection would be used by inbound car traffic and
93 outbound bus traffic to circulate between H Street and the deck. The intersection would be
94 approximately where the existing parking garage entrance is located. Its south leg would have
95 two inbound lanes and one outbound lane. The intersection would provide access from H Street
96 to a new road along the west side of the Project Area (west road). Private and for-hire cars would
97 use it to reach the pick-up and drop-off area adjacent to the train hall via a ramp rising above the
98 bus facility. Bus leaving the bus facility would use it to leave the site. At the intersection,
99 outbound buses could turn left (westbound) or right (eastbound) onto H Street NE.
- 100 ■ **East Intersection:** The new east intersection would be used by outbound car traffic and inbound
101 bus traffic. It would be just to the west of the existing driveway serving the nearby Kaiser
102 Permanente building. Its south leg would have one inbound lane and two outbound lanes. The
103 east intersection would be used by private and for-hire vehicles leaving the pick-up and drop-off
104 area adjacent to the train hall via the new east road. It would also be used by buses entering the
105 bus facility from H Street NE.

106 As the result of the proposed intersections' configuration, WUS-related pick-up and drop-off traffic would
107 travel counterclockwise on the deck, looping from west to east via the train hall's pick-up and drop-off area.
108 Conversely, bus traffic would travel clockwise, looping from east to west via the bus facility. In case of
109 planned or unplanned road or lane closures, these circulation patterns could be temporarily modified. The
110 bicycle and pedestrian ramps on the east and west sides of WUS, respectively, could then be used by buses
111 (east ramp) or cars (west ramp). This operating condition would be rare and temporary.

⁷ **Figure S-6** is intended to illustrate WUS-related traffic movements only. Roadway alignments are approximate.

⁸ Traffic to and from the private air rights development could also use these roadways if, as assumed in this EIS, both projects are built. Intersections and roadways exclusively needed for private air rights development use are not part of the Project and, as such, are not described in this section.

Figure S-6. Deck Circulation in Alternative F

S.6 Bus Facility

112 In Alternative F, the bus facility would be integrated into the deck and extend from east to west, parallel and
113 adjacent to the entire length of the train hall. **Figure S-7** illustrates the layout of the bus facility. The facility
114 would be for use by intercity and tour or charter buses only. It would not accommodate transit buses or hop-
115 on/hop-off sightseeing buses.

116 The bus facility would be adjacent to and directly connected to the train hall's lower mezzanine level, where
117 bus passenger amenities would be located. This would ensure optimal integration with the remainder of
118 WUS and emulate the connectivity between the train hall and the tracks and platforms. Bus passengers
119 would have convenient access to the vertical circulation elements that would bring them to Concourse A, the
120 historic station, and lower-level concourses and Metrorail. **Figure S-8** and **Figure S-9** illustrate the
121 relationship of the bus facility to the train hall.

Figure S-7. Conceptual Layout of the Bus Facility in Alternative F

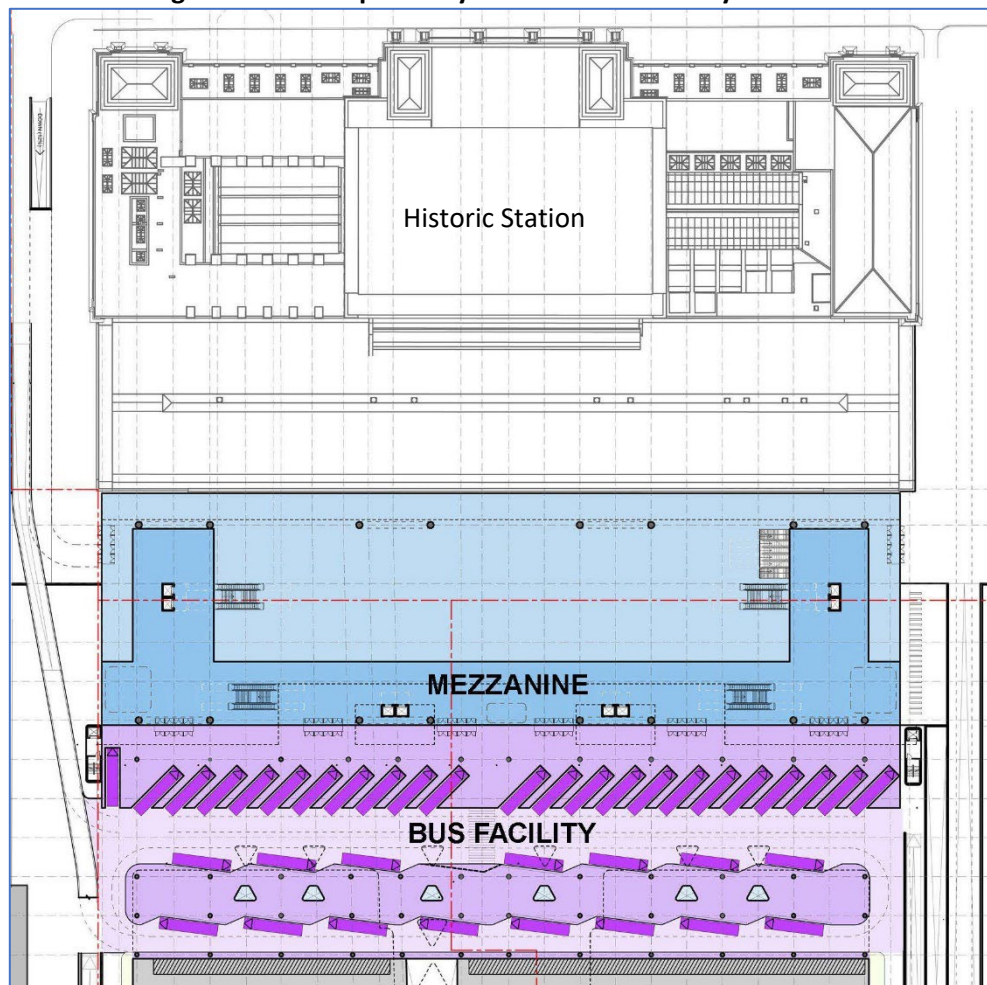

Figure S-8. Conceptual Rendering of Mezzanine Level of Train Hall in Alternative F (Looking East)

Figure S-9. Conceptual Rendering of Bus Facility in Alternative F (South Side, Looking East)

122 A glazed wall would separate the mezzanine from the bus facility, which would be semi-opened and
123 ventilated. The facility would consist of two loading/unloading areas. Along the south side, directly adjacent
124 to the mezzanine, a total of 23 angled bus slips would be provided. Across the bus circulation lane from this
125 area, another 15 slips would be arrayed around an island, with room for a 16th slip for use if and as needed,
126 for a total of 38-39 bus slips.

127 Buses would reach the facility from H Street NE eastbound only via the new east intersection and east road.
128 They would exit the facility toward H Street NE via the new west road and the west intersection. At the west
129 intersection, buses could turn left onto H Street NE westbound or right onto H Street NE eastbound.

130 The Federal Railroad Administration (FRA) and the Project Proponents (Union Station Redevelopment
131 Corporation [USRC] and Amtrak) anticipate that the bus facility operations would employ a dynamic
132 management approach, but that dedicated slips may also be provided. FRA and the Proponents will continue
133 coordinating with the bus operators on the most effective management approach. The facility would provide
134 infrastructure for bus electric charging.

135 FRA and the Project Proponents have determined that the size of the facility would be sufficient to meet
136 anticipated future (peak) intercity demand, including during holidays and other periods of predictable high
137 travel demand such as large events in the area. However, it is possible that occasionally (exceptional peak)
138 tour and charter bus demand may exceed the capacity (for instance, during the Cherry Blossom Festival or
139 large demonstrations in the District of Columbia). In such cases, which are anticipated to be infrequent, the
140 deck-level pick-up and drop-off area alongside the train hall (above the bus facility) could be used to load and
141 unload bus passengers. This area could provide the equivalent of approximately 15 slips for additional
142 charter buses. FRA and the Project Proponents would coordinate with the bus operators to develop
143 procedures for how and when these 15 slips would be used.

S.7 Parking

144 In Alternative F, all automobile parking would be on one below-ground level, underneath the tracks and the
145 concourses, along the west side of the rail terminal. Parking would be collocated with a pick-up and drop-off
146 facility (See **Section S-9, Pick-up and Drop-off Areas**, below). The exact layout of both uses is still under
147 development. As a result, the exact number of parking spaces that would be provided has not yet been
148 determined but would be between approximately 400 and 550. These spaces would be for long-term
149 parking, short-term parking, and rental car parking. Again, the exact distribution among these three types of
150 parking has not yet been determined. In general, most parking would be in the portion of the below-ground
151 facility north of H Street NE, while most of the portion south of H Street NE would be used for pick-up and
152 drop-off activities. Provisions for electric vehicle (EV) charging would be made in the parking facility.

153 Vehicles would enter or exit the parking facility either via a new ramp on G Street NE or via a new ramp on
154 First Street NE. The ramp on G Street NE would have two lanes. It would be in the middle of the right-of-way.
155 Inbound vehicles would reach the ramp via North Capitol Street. Outbound vehicles would turn right or left
156 from the ramp onto North Capitol Street. There would be a surface lane on each side of the ramp for traffic
157 between First Street NE and North Capitol Street. Reconfigured G Street NE is illustrated in **Figure S-10**.

Figure S-10. G Street NE in Alternative F

158 The ramp on First Street NE would be located between H Street NE and K Street NE, creating an opening in a
159 non-original portion of the Burnham Wall. It would be bidirectional and served by a signalized intersection.⁹
160 Outbound vehicles could turn left or right onto First Street. Inbound access would be via a right turn from
161 First Street NE northbound only. The location of the First Street Ramp is shown in **Figure S-14** below.

S.8 Pedestrian and Bicycle Access

S.8.1 Front of WUS

162 The front of WUS is the main access point to the station for pedestrians and cyclists. It would largely remain
163 so in alternative F, due to its direct connection to the District of Columbia’s larger pedestrian and bicycle
164 network and to Capitol Hill. Existing pedestrian and bicycle facilities at the historic station building include a
165 wide sidewalk in front of the building; pedestrian islands on both its east and west sides for easier and safer
166 navigation; a two-way cycle track starting on First Street NE; and a Capital Bikeshare station on the east side.
167 Currently, pedestrians must use four crosswalks to cross from WUS to the west side of First Street NE. In
168 Alternative F, pedestrians would need to navigate only one crossing, as illustrated in **Figure S-11**. First Street
169 NE, currently a two-way road, would become one-way northbound up to G Street NE, eliminating the need
170 for a right-turn lane to Massachusetts Avenue NE and widening the pedestrian zone in the southwest corner
171 of the station.

⁹ Signalization approach subject to warrant analysis and coordination with DDOT.

Figure S-11. Proposed Pedestrian Changes at Front of Station in Alternative F

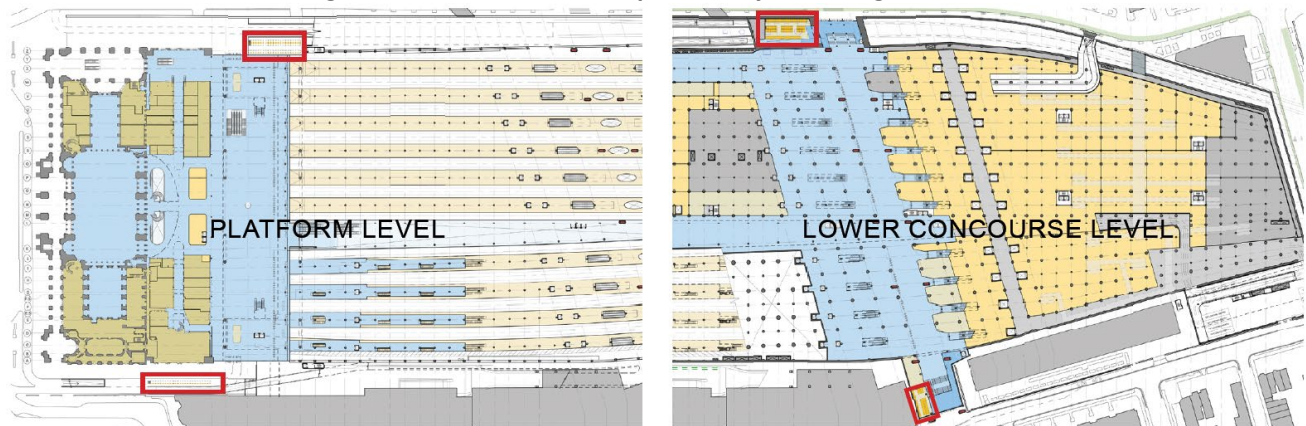

172 The existing cycle track would remain on the east side of First Street NE, with modifications to improve safety
173 by minimizing conflicts with pick-up and drop-off activities at the new entrance at First and H Streets NE. The
174 existing ramp along the west side of WUS, which connects H Street NE to the western end of Columbus Circle
175 and First Street NE, would be replaced with a pedestrian and bicycle ramp to the deck level and H Street. On
176 the east side of WUS, another pedestrian and bicycle ramp would provide access to the bus facility.¹⁰

177 Bicycle storage and parking facilities would be constructed in the undercroft of both ramps, adjacent to the
178 train hall. Bicycle storage and parking space would also be provided in the H Street Concourse, near the
179 entrances from First and Second Streets NE, respectively, and accessible from the bicycle facilities on either
180 street. Bicycle storage capacity would be approximately 900 bicycles, including at least 50 short-term bicycle
181 racks. Additionally, approximately 100 additional bikeshare spots with electrical power would be provided.
182 The location of the bikeshare spots and short-term racks would be coordinated with the District Department
183 of Transportation (DDOT). Bicycle storage facilities are shown in **Figure S-12**. These facilities would be built in
184 compliance with District of Columbia’s bicycle parking guidelines.¹¹

¹⁰ As noted above, these ramps could occasionally be used to move vehicles when needed, but this would not be a common occurrence. Because of this possibility, the ramps are shown as a shared-use facility in **Figures S-11 and S-13**.

¹¹ DDOT. 2018. *Bike Parking Guide*. Accessed from https://ddot.dc.gov/sites/default/files/dc/sites/ddot/publication/attachments/DDOT%20bike%20parking%20guide_060118_Screen.pdf. Accessed on March 12, 2023.

Figure S-12. Location of Proposed Bicycle Storage Facilities

Red boxes indicate bicycle storage locations.

S.8.2 First Street NE

185 Alternative F would feature an entrance to the new H Street Concourse on First Street NE. This entrance
186 would have to accommodate a high number of pedestrians; therefore, the sidewalk at this location would be
187 widened. As noted above, new bicycle storage would be provided at this location. There would also be a new
188 bikeshare station on the west side of the street, under the H Street Bridge. The First Street cycle track would
189 remain on the east side of the street.

S.8.3 Second Street NE

190 Similarly, an entrance to the H Street Concourse would be provided on Second Street NE, under the H Street
191 Bridge. Like the First Street entrance, the Second Street entrance would feature a wider sidewalk. New
192 bicycle storage and a new bikeshare station on the west side of the street under the bridge would also be
193 provided. Together, the east and west entrances to the H Street Concourse would provide pedestrian
194 connectivity between the neighborhoods to the east and west of WUS.

S.8.4 H Street NE

195 Alternative F includes pedestrian access to the new concourses from H Street NE via two headhouses. These
196 headhouses would be on the south and north sides of the street, respectively, about mid-block. They could
197 be integrated with the surrounding private air rights development.

S.9 Pick-up and Drop-off Areas

S.9.1 Below-Ground Pick-up and Drop-off Facility

198 The primary location of pick-up and drop-off activities in alternative F would be the below-ground facility
199 collocated with parking under the tracks and concourses. This facility would account for approximately half of
200 all WUS-related pick-ups and drop-offs.

201 The exact layout of, and circulation patterns within, the below-ground pick-up and drop-off facility would be
202 defined as part of the design process. In general, the facility would include an area for vehicle staging and
203 queueing at its southern end, and an area for passenger loading and unloading adjacent to the queuing area.
204 Vehicles would enter and exit the facility via the G Street NE ramp and First Street ramp described in
205 **Section S.7, Parking**, above. As technically feasible, provisions for EV charging would be made in the
206 queueing and staging areas.

207 In the boarding area, passengers would wait for their rides on one of several islands. From the staging and
208 queuing area, vehicles would proceed to the boarding islands within the facility. Taxis would also exit via a
209 new ramp on the east side of the station to pick up passengers at the main station's entrance on Columbus
210 Circle. The location of this ramp on the east side of the station can be seen in **Figure S-13** below.

S.9.2 Front of WUS

211 There are currently six lanes of traffic on the north side of Columbus Circle in front of WUS. Traffic moves
212 counterclockwise around the circle. Upon reaching the front of the station, the two-lane approach from the
213 southeast splits into a two-lane pick-up and drop-off area (south lanes) and a two-lane bus area (central
214 lanes) for hop-on/hop-off sightseeing buses. North of the two bus lanes are two more lanes (north lanes)
215 used for taxi pick-up activity. These taxis access the circle using the east ramp that connects to the existing
216 parking garage and H Street NE. The east ramp currently allows vehicle flow in both directions. However,
217 taxis may only circulate southbound and general traffic may only circulate northbound.

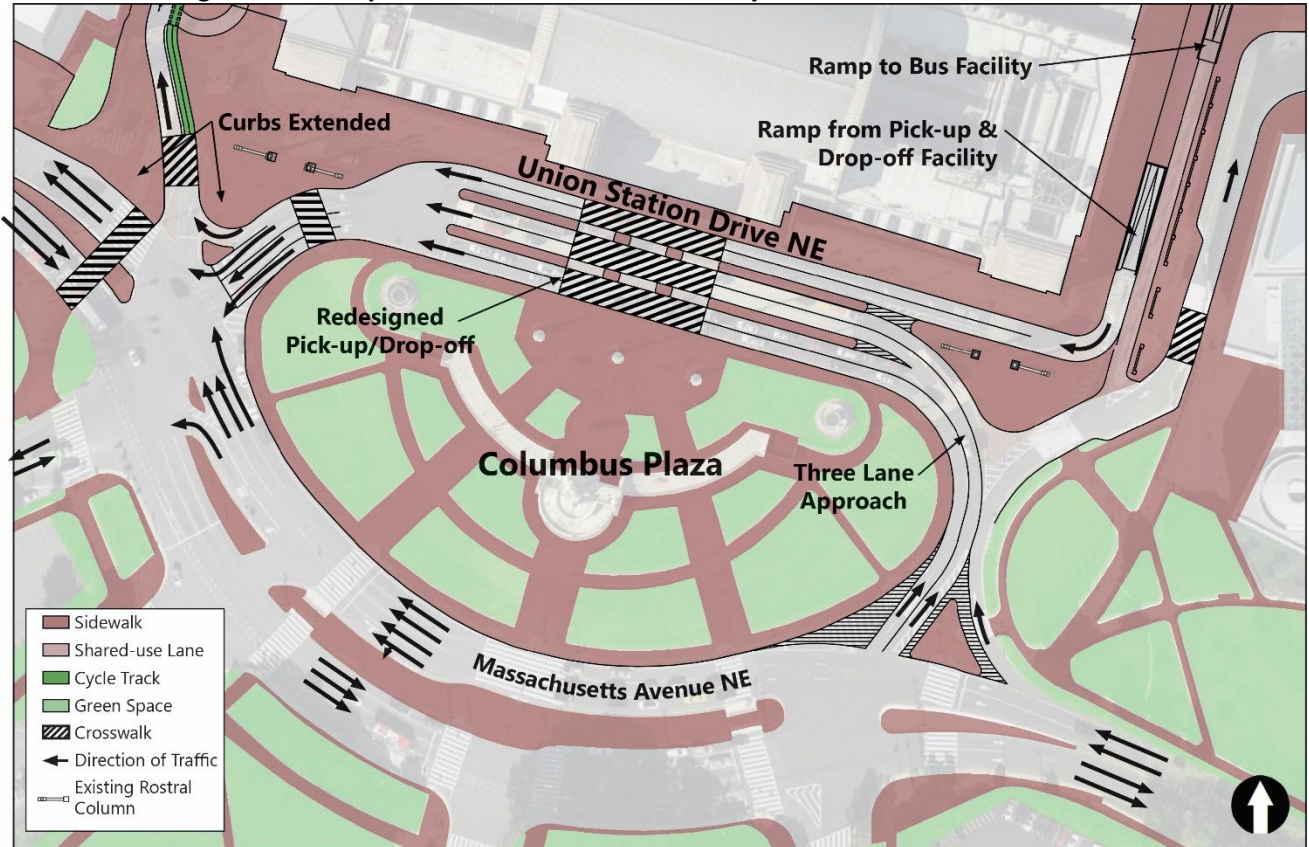

218 The pick-up and drop-off lanes (south lanes) and the taxi lanes (north lanes) are 9 feet wide each and the bus
219 lanes (central lanes) are 12 feet wide. Eight-foot-wide medians separate the three sets of lanes. At the
220 western end of the circle, the three sets of lanes, together with the existing southbound ramp from H Street
221 NE, merge into three lanes by which vehicles can exit to Massachusetts Avenue (eastbound or westbound) or
222 E Street NE (southbound).

223 In Alternative F, the six existing lanes in front of the historic station building would remain. The south lanes
224 would be used for passenger drop-off and the central lanes for transit bus stops. Taxis would continue to
225 have the exclusive use of the north lanes. As explained above, taxis would reach the front of WUS via a ramp
226 from the below-ground pick-up and drop-off facility.

227 At the western end of the circle, three exit lanes to Massachusetts Avenue and E Street would be maintained.
228 The existing connection with the southbound ramp would be eliminated and replaced with a fourth exit lane
229 providing northbound access to First Street NE.

230 Alternative F also includes changes to the circle's approaches on the east side. A third lane would be added
231 to the approach from the southeast to minimize queuing. The connection for vehicles traveling northbound
232 from Massachusetts Avenue NE and Columbus Circle to F Street NE would stay as it is now. However, on the
233 left side of that segment, there would be two pick-up and drop-off spaces for use by WUS commercial
234 tenants. **Figure S-13** illustrates the proposed improvements in front of WUS.

Figure S-13. Proposed Columbus Circle Roadway Modifications in Alternative F

S.9.3 Deck Level

235 At deck level, there would be a pick-up and drop-off area along the north side of the train hall, above the bus
236 facility, just outside the upper mezzanine. Vehicles would access this area via the west intersection and west
237 road and exit it via the east road and east intersection. The deck-level pick-up and drop-off area would
238 provide space for approximately 22 cars. As noted above in **Section S.6, Bus Facility**, on days of exceptionally
239 high demand for intercity bus travel, the area could be used infrequently for bus rather than car loading and
240 unloading.

S.9.4 First and Second Streets NE

241 In addition, room for limited pick-up or drop-off activities would be provided on First Street NE
242 (approximately 13 spaces) and Second Street NE (approximately eight spaces). The below-ground pick-up and

243 drop-off facility, deck-level pick-up and drop-off area, and the front of WUS would account for most pick-up
 244 and drop-off activity at WUS. The areas on First and Second Streets NE would be near the entrances to the H
 245 Street Concourse. On First Street NE, the pick-up and drop-off spaces would be provided on the west side of
 246 the street, north of the H Street Concourse. The First Street cycle track would remain on the east side of the
 247 street. To accommodate this pick-up and drop-off space, the existing parking and loading lane along the west
 248 curb would be converted to an active pick-up and drop-off curbside. This change would be accommodated
 249 within the existing curbs and there would be no change to other existing lanes. As needed, lane shifting and
 250 restriping would be used to facilitate safe operations and to limit congestion. Pick-up and drop-off facilities
 251 on First and Second Streets NE are illustrated in **Figure S-14**.

Figure S-14. First Street and Second Street NE North of H Street in Alternative F

S.10 Intercity and Commuter Rail Operations and Ridership

252 Alternative F would allow intercity, commuter and transit rail passenger volumes to grow as shown in
 253 **Table S-1**. The estimates are the same across all Action Alternatives, with Virginia Railway Express (VRE)
 254 having the greatest projected increase: 187 percent increase in service accommodating an almost 250
 255 percent increase in passengers. Amtrak and Maryland Area Regional Commuter (MARC) trains would also
 256 experience substantial increases in passenger volumes and service.

257 **Table S-1** shows the changes in levels of service that would occur for each service to accommodate the
 258 increased ridership. To accommodate these increased volumes, each full day, Amtrak would operate 57 high-
 259 speed trains per direction, 23 intercity trains per direction, and 6 long distance trains per direction.

260 Additionally, Amtrak would run 58 Metropolitan trains per direction daily. MARC full-day service would
 261 consist of 57 Penn Line trains, 30 Camden Line trains, and 38 Brunswick Line trains per direction. Of 14 peak-
 262 hour Penn Line trains, it is anticipated that eight would continue to Virginia. For VRE, daily, 23 trains per
 263 direction would run on the Fredericksburg Line and 23 trains per direction would run on the Manassas Line.

Table S-1. Estimated Train Passengers and Volumes by Service

Service	Existing Passenger Volumes	2040 Passenger Volumes	Train Volume Increase over Existing
Amtrak	16,400 daily 5.033 million annually	32,000 daily (+95%) 9.070 million annually	148%
MARC	28,100 daily 7.683 million annually	70,700 daily (+152%) 19.293 million annually	163%
VRE	3,900 daily 1.060 million annually	13,600 daily (+249%) 3.706 million annually	187%

S.11 Construction Methods and Activities

264 FRA and the Project Proponents evaluated the constructability of the Project by considering the following
 265 factors: sequencing, duration, needed equipment, staging, traffic routing, materials removal, excavation, and
 266 dewatering. A detailed constructability analysis concluded that all the Action Alternatives presented in the
 267 2020 Draft Environmental Impact Statement (DEIS) are constructible. However, they would vary in their
 268 construction duration and cost based primarily on the depth of excavation associated with each alternative.¹²

269 Alternative F would be similar to the 2020 DEIS Action Alternatives with regard to the key constructability
 270 factors. This section presents a summary of the construction activities associated with Alternative F.

S.11.1 Construction Phasing and Sequence

271 After reviewing different potential approaches for construction, the Project Proponents, with participation
 272 from FRA, determined that in all Action Alternatives, construction would proceed in four sequential phases.
 273 This approach would adequately balance the need to maintain an acceptable level of train service
 274 throughout the construction period while allowing construction to proceed in a reasonable amount of time.
 275 At a minimum, three low-level, run-through platforms would be in operation at all times, which is necessary
 276 to adequately maintain VRE, long-distance train operations, and regional run-through service. During each
 277 phase, a set number of tracks and platforms would be taken out of service and become an active
 278 construction zone. The width of the construction area during each phase would be dependent on the
 279 maximum number of tracks that can be removed while maintaining adequate rail operations and space for
 280 construction activities. The minimum average phase width would be approximately 90 feet.

281 The construction sequence would follow the same general approach within each phase. A set of tracks would
 282 be taken out of service. Temporary tracks and connections would be constructed as needed to maintain

¹² Amtrak. November 2019. *Washington Union Station Terminal Infrastructure Project Constructability Report*.

283 operations and potentially support the operation of work trains. Cut-off and support walls (see
284 **Section S.11.2, Support of Excavation**, for more details) would be installed to support excavation and keep
285 groundwater out. Following excavation, drilled shafts would be constructed to provide deep foundations for
286 the slabs supporting the new tracks and the columns supporting the deck on which the Project elements
287 would stand. As construction moves to the next phase, the deck-level Project elements would be
288 constructed.

289 The First Street Tunnel column removal work (see **Section S.1, Tracks and Platforms/Rail Support Function**)
290 would take place in three sequential phases, also from east to west. Work would follow approximately the
291 same pattern during each phase: strengthening and modifying the structural connections of the tunnel
292 columns to be maintained; replacing or strengthening the overhead tunnel roof beams to span across the
293 gaps created by the removal and replacement of the existing columns and crash walls; removing select
294 existing columns and crash walls; finalizing tunnel deck substructure improvements as needed; and shifting
295 the tracks.

296 The column removal work would be conducted simultaneously, and largely overlap, with the main
297 construction effort. The first phase of the column removal work would take place during Phase 1 of the main
298 construction and the third phase would take place during main construction Phase 2. To maintain adequate
299 levels of rail service, the second phase of the column removal work must start after main construction Phase
300 1 is complete and be finished before main construction Phase 2 begins. Therefore, there would be a period –
301 anticipated to extend over approximately 12 months – between Phase 1 and Phase 2 during which only
302 column removal work would be conducted.

S.11.2 Support of Excavation

303 Construction of Alternative F would require excavating the stub-end portion of the rail terminal. The
304 maximum depth of excavation would be approximately 49 feet below existing grade (3 feet above mean sea
305 level).

306 Walls would be needed to support the excavation and control groundwater seepage. The constructability
307 review for Alternative F indicated that the appropriate support of excavation (SOE) would involve a 100-foot-
308 deep slurry wall around the stub-end tracks portion of the rail terminal, which would be excavated to build
309 the proposed below-ground pick-up and drop-off and parking facility.¹³ This wall would reach down to the
310 Potomac Clay layer underneath WUS. As such, it would isolate the construction site from the underlying
311 upper aquifer and would be sufficient to prevent excessive groundwater seepage into the Project area.

¹³ Constructing a slurry wall involves excavating a trench that is simultaneously filled with a mix of bentonite and water (slurry), which keeps the trench from collapsing. The trench is then filled with concrete from the bottom up after installation of reinforcing steel. The concrete displaces the slurry as the trench fills up and hardens around reinforcement to form a structural wall.

312 The excavated portion of the run-through tracks area of the rail terminal would be surrounded by a 64-foot-
313 deep secant-pile wall.¹⁴ Sixty-four-foot-deep sheet-pile walls would be used to separate construction phases
314 and establish passageways for construction trucks and equipment.¹⁵

S.11.3 Excavation Method

315 The constructability analysis of the Project assessed both open-cut and top-down construction techniques.
316 Open-cut, or traditional excavation methods, would build the Project by excavating a trench within the
317 construction area and then building upwards to the completion of each phase. Top-down construction would
318 build the Project by first rebuilding the track level, structural supports, and deck above, then completing the
319 below-ground portions after the above-grade elements are sufficiently complete.

320 FRA determined that the EIS would assess the open-cut construction approach for all Action Alternatives,
321 including Alternative F, for the following reasons. Open-cut construction would be less expensive and take
322 less time than top-down construction. The open-cut approach would also allow for easier access to the
323 excavation area; provide more staging space; and make it easier to use work trains for excavation spoil
324 removal.

S.11.4 Drilled Shaft Construction

325 Drilled shafts would be the foundation for track support and other Project elements, including supporting
326 decks. Drilled shafts for the Project in Alternative F would range in diameter from 4.33 feet to 10.5 feet.¹⁶
327 Average depth would be up to approximately 150 feet. Construction of a drilled shaft would involve drilling a
328 hole, stabilizing it using either a casing or a slurry, installing reinforcing bars, and filling the hole with
329 concrete.

S.11.5 Construction Equipment

330 Several elements of the Project would require the use of large construction equipment:

- 331 ■ Three major construction operations would require large cranes: SOE, drilled shaft construction,
332 and construction of the superstructure supporting the Project's above-ground elements. These
333 operations would require cranes with boom lengths of 150 to 250 feet.
- 334 ■ Construction of drilled shafts would involve the use of large drilling rigs. A typical drilling rig
335 would be approximately 88.5 feet tall.

¹⁴ Secant-pile walls are made of intersecting reinforced concrete piles reinforced with either steel rebar or steel beams. The piles are installed by drilling into the ground.

¹⁵ Sheet-pile walls consist of prefabricated steel wall sections driven into the ground. The joints of adjacent sections are connected to form the full wall.

¹⁶ Amtrak. August 2022. *Washington Union Station Terminal Infrastructure Project Cost and Schedule Analysis: Revised Alternative*.

336 ■ Concrete production may require the installation of a small concrete batch plant, likely in the
337 West Rail Yard.¹⁷

338 ■ Construction of a slurry wall would require setting up a slurry plant.¹⁸

339 The setting of the Project in a dense urban environment and active rail terminal would affect the type of
340 equipment used for construction. Equipment must be able to maneuver in cramped conditions and minimize
341 disruption to adjacent areas.

S.11.6 General Construction Site Access and Staging

342 The constructability analysis identified five potential areas for construction site access and staging (see
343 **Figure S-15**). Construction staging areas would be used to lay down materials, stage equipment and
344 personnel, and set up concrete batch plants. Other construction activities, such as the slurry plant, would
345 move with the construction work from phase-to-phase.

Figure S-15. Potential Site Access and Staging Locations

¹⁷ A concrete batch plant is a piece of equipment that combines various ingredients to produce large amounts of concrete. Ingredients include but are not limited to water, air, sand, aggregate (such as rocks or gravel), and cement. The concrete batch plant would be a different piece of equipment from the slurry plants mentioned in the following bullet.

¹⁸ A slurry plant or slurry mix plant is a piece of equipment that produces the slurry used for the construction of slurry walls. Bentonite slurry is produced by mixing bentonite powder and water in a high-shear mixer.

346 The five staging areas are:

- 347 ■ **Access Ramp:** The east loading dock access ramp and local roads (First Street, Second Street, H
348 Street) would serve as access points for personnel, minor equipment, and limited material.
- 349 ■ **H Street Tunnel:** The H Street Tunnel would serve as a major access point for all phases of
350 construction. It would serve as access for personnel, equipment, and materials. After the
351 completion of Phase 1, construction access would be at First Street NE only.¹⁹
- 352 ■ **West Yard:** The west yard would serve as a major staging area for all phases. It would be used for
353 deliveries and potential excavation spoil removal by work trains. It may also potentially serve as a
354 location for the small concrete batch plant.
- 355 ■ **REA Parking Lot:** The REA Parking Lot would serve as a major access point during construction for
356 personnel, equipment, and materials. It may also serve as a potential staging area for
357 construction materials.
- 358 ■ **Train Access Area:** This area would provide access for work trains during the construction period.
359 Materials may be delivered and removed by train to reduce truck volumes during construction.

360 As construction proceeds, some space on the deck may be available for construction staging as well.

S.11.7 Station Access During Construction

361 Construction activities would disrupt the various transportation modes serving WUS, though the modes
362 affected, and the level of disruption would vary with the phase. Operations would be maintained, as much as
363 possible, to minimize disruptions to the traveling public.

S.11.7.1 Taxi

364 Construction would require the closure and removal of the taxi queue along the east ramp and back of the
365 Claytor Concourse starting in Phase 1. Passenger pick-up and drop-off would remain available in front of
366 WUS. Alternative routes and queuing locations would be provided. Depending on the construction phase,
367 these may include the west ramp to the front of the historic station building, Second Street NE, and the
368 completed portions of the desk via H Street NE.

S.11.7.2 Bus

369 During Phase 3 of Project construction, partial demolition of the existing parking garage would require the
370 relocation of the bus facility to the unaffected portion of the structure. In Phase 4, the remainder of the
371 existing parking structure would be demolished. If needed during Phase 3 and during the entirety of Phase 4,
372 a temporary bus facility or temporary bus loading zones would be established on the completed portion of
373 the structural deck, including the private air rights deck. These temporary facilities would be of sufficient size
374 to maintain an adequate level of operations. Prior to beginning demolition of the existing structure, USRC

¹⁹ The H Street tunnel is the former alignment of H Street NE between First and Second Streets, now under the rail terminal.

375 and the private air rights developer would develop an agreement establishing the conditions under which
 376 some of the private air rights deck would be made available for WUS bus operations.

S.11.7.3 Parking

377 Starting in Phase 1, construction would eliminate vehicular access to the existing parking garage via the
 378 existing east ramp. Pedestrian access would remain available. Partial demolition of the existing garage would
 379 start during Phase 3 and the remainder of the facility would be demolished during Phase 4. During Phase 4,
 380 parking would be unavailable at WUS.

S.11.7.4 Construction Equipment and Access

381 Construction equipment and material staging would take place in the REA Building Parking Lot south of K
 382 Street NE (Phase 1) and the West Yard (Phases 1 through 3 and half of Phase 4). After completion of Phase 1,
 383 parts of the east deck would potentially be available for staging as well. The west side of the H Street Tunnel
 384 would be the main access point during all phases. The east side of the tunnel would provide access during
 385 Phase 1, but it would be demolished as part of the excavation of this phase.

S.11.8 Duration of Construction

386 The construction analysis for Alternative F estimated that it would take a total of approximately 13 years to
 387 complete. **Table S-2** shows the respective durations of the various construction phases, along with how much
 388 of each phase would be devoted to excavation activities.

Table S-2. Estimated Construction Schedule of Alternative F

Phase	Duration	Excavation Duration
Phase 1	2 years 4 months	5 months
Intermediate Phase (column Removal)	12 months	None
Phase 2	2 years 8.5 months	10 months
Phase 3	2 years 8.5 months	11 months
Phase 4	4 years 3 months	2 years 1 month
Total	13 years	4 years 3 months

S.11.9 Removal and Transport of Materials

389 Spoils containing rocks and soils would be removed throughout excavation operations. Hydrocarbons, heavy
 390 metals, and polychlorinated biphenyls may be present in the spoil in excess of regulatory thresholds.
 391 Contaminated materials would be disposed of in compliance with applicable laws and regulations. The
 392 estimated amount of spoil materials that would be removed in Alternative F is approximately 1,507,102 cubic
 393 yards.

394 Removal of excavation spoil from the site would be by trucks or work trains, or a combination of both. Based
 395 on the estimated amount of spoil that would need to be disposed of, removal by trucks only would require
 396 up to 120 truck trips a day, spread over a 20-hour day, in addition to 10 to 20 truck trips for deliveries.
 397 Alternatively, spoil removal could be by work train. Two 20-gondola work trains a day would be sufficient to

398 haul off the same amount of spoil as 120 trucks. This would limit daily truck traffic to the 10 to 20 delivery
399 trips a day previously mentioned. The work trains would be scheduled in a manner that does not interfere or
400 conflict with Amtrak, VRE, or MARC operations. Amtrak has not yet determined the feasibility of using work
401 trains for spoil disposal while maintaining an adequate level of operations. Therefore, where appropriate, the
402 impact analysis considers two removal scenarios: removal by trucks only and removal by work trains.
