Introduction

Description and Objective

The Federal Railroad Administration (FRA) developed GradeDec.Net as an investment decision support tool for use by state and local authorities. The careful analysis and selection of highway-rail grade crossing investments serves to increase public returns for each dollar invested.

GradeDec.Net is a web-based application that enables the analysis of impacts from grade crossing improvements and supports resource allocation and investment decisions. It allows state and local decision makers to prioritize highway-rail grade crossing investments based upon an array of benefit-cost measures. GradeDec.Net evaluates the benefit-cost of grade crossing improvements while explicitly reporting the results for each grade crossing and each benefits category (safety, time savings, vehicle operating costs, reduced emissions, network and local benefits).

Localities can use GradeDec.Net to focus on the benefit metric of greatest local interest. For instance, an area marked by high levels of highway congestion at grade crossings can identify the improvements that offer the prospects for congestion mitigation. For a rural area with acute safety issues, GradeDec.Net assists in identifying the investments that will promote accident reduction.

GradeDec.Net facilitates a structured analysis. The analysis process in GradeDec.Net is as important as the end result. GradeDec.Net can be useful as a tool for managing data and partial analyses and does not require that users take advantage all of its features. For instance, users can import data and conduct safety analyses without defining alternatives and running a full investment analysis.

A GradeDec.Net investment analysis finds the economic rate of return for a specified program of highway-rail grade crossing investments in a corridor or region. The economic rate of return is appropriate for measuring public returns because it captures a wide range of benefits that accrue to users of the transportation system and society as a whole, i.e., reductions in accidents and emissions, time and vehicle operating cost savings. GradeDec.Net calculates the economic rate of return by comparing the streams of expected economic benefits over time with the streams of investment, operating and maintenance and other life-cycle costs. The model discounts later year benefits and costs to reflect the opportunity cost of capital. This process of discounting converts all
values to present value equivalents thus enabling the comparison of benefits and cost realized in different time periods.

*GradeDec.Net*’s analysis of grade crossing improvements is both at the individual grade crossing and at the corridor or regional level. Outputs include result metrics for the individual grade crossings and for the corridor or region as a whole. A series of up to 600 grade crossing improvements can be evaluated simultaneously. *GradeDec.Net* also reports an array of intermediate result metrics that are useful in interpreting the results.

*GradeDec.Net*’s underlying methodology is consistent with the current benefit-cost methodologies employed by United States Department of Transportation Agencies (Federal Railroad Administration, Federal Highway Administration, Federal Transit Administration, and Federal Aviation Administration) and with Executive Order 12893, which governs the principles of federal infrastructure investment. *GradeDec.Net* can be used to comply with the Office of Management and Budget's *Guidelines for Benefit Cost Analysis* specified in Circular No. A-94. The model is transparent in all of its assumptions and model inputs are readily accessible to users who may wish to adjust them to more closely reflect local conditions.

*GradeDec.Net* integrates several modeling capabilities in a single package. It includes separate modeling modules for corridor and regional analysis. The corridor analysis module evaluates crossing improvements along a single rail alignment. The corridor analysis accounts for impacts on the adjacent highway network and shifts in highway to routes with improved crossings. The module for regional analysis evaluates crossing improvements in a region (county or several counties) regardless of the crossings being located on a single or multiple rail alignments.

Both the corridor and the regional analysis modules of *GradeDec.Net* include the US DOT Accident Prediction and Severity Model. The corridor analysis module includes as well the grade crossing risk mitigation model for high speed rail that was developed by the Volpe National Transportation Systems Center.

*GradeDec.Net* includes a risk analysis modeling capability. This capability enables the user to accommodate the numerous uncertainties that are inherent in any forecast. Rather than relying on "best guess" inputs whose actual values may vary widely, risk analysis incorporates input ranges. For a designated set of operational and policy variables in *GradeDec.Net*, users can set ranges describing probability distributions. These ranges reflect best available data and empirical evidence combined with any expert judgments that the user brings to bear in the analysis. *GradeDec.Net* includes a graphical interface that facilitates data entry and the visualization of probability distributions. *GradeDec.Net* presents its results, the outcomes of risk analysis simulations, as probability distributions. These results and their mode of presentation support informed decision-making by providing the full range of possible outcomes rather than relying upon a point estimate.
GradeDec.Net represents a major upgrade from GradeDec 2000, the previous release of GradeDec. It incorporates additional analytic algorithms and handles many more grade crossings simultaneously. GradeDec.Net strives to meet the needs of both experienced and novice users. Experienced analysts can take advantage of newer features and capabilities while less experienced analysts can rely upon pre-defined default values and should find GradeDec.Net easy to use for conducting an analysis.

GradeDec.Net has been available to the public since January 2003. In the two years since its initial release, the GradeDec.Net model has undergone refinements that reflect experience gained from hundreds of analyses and feedback from the community of over 500 registered users and training workshop participants.

The main refinements to the GradeDec.Net model since it was introduced include:

- Ability to develop a capital program of improvements with two-phased investment at each crossing (and not just assuming that all investment occurs prior to the period of analysis).
- Explicit segmentation of time-of-day distributions for passenger, freight and switch train movements (in the corridor model, and for through and switch train movements in the regional model).
- Increasing from one to three the number of placeholder “new technology” options for grade crossing devices.
- Creating three placeholder options for “other supplementary safety devices” at crossings.

In addition to these modifications, there are a number of refinements to the application interfaces and reporting features that should facilitate the development of analyses with GradeDec.Net. These refinements are covered in the revision the companion GradeDec.Net User’s Manual.

**About This Document**

This document is the reference for the GradeDec.Net model. The remainder of this document presents the model components, the computation algorithms, and descriptions of the data inputs to the model.

In order to best utilize the GradeDec.Net application you should refer to the companion volume to this document called "User’s Manual for GradeDec.Net".

This document is not a benefit-cost analysis manual. It assumes that readers are generally familiar with benefit-cost analysis, its application and some basic concepts like present value and rate of return. Useful references for using benefit-cost analysis can be found in NCHRP Report No. 342, the AASHTO Redbook and Transport Canada's Benefit-Cost Manual.
Model Overview

Introduction

*GradeDec.Net* is a grade crossing investment analysis tool that includes both a platform for organizing the data for your analysis and a computational risk analysis model. This Overview presents the frame of analysis, the computational model and the data and their organization.

The Analysis Frame of *GradeDec.Net*

The analysis frame of *GradeDec.Net* considers a proposed set of grade crossing investments on a rail corridor, or a region, over a specified time horizon. The analysis of benefits and costs compares the present value of costs and benefits in the "alternate case" (with major investment) to the costs and benefits in the "base case" (without major investment).

The following are the definitions and assumptions for the *GradeDec.Net* analysis frame:

**Benefits and Costs**

The benefits in a *GradeDec.Net* analysis are the public benefits that accrue from grade crossing improvements. These include:

- Safety – the safety benefits are the reduction in predicted accidents and their severity.
- Other user cost savings – other user cost savings result from less queuing at crossing due to grade crossing separations and closures. These benefits are travel time savings, reduced highway vehicle operating costs, reduced emissions and better highway network traffic flow. Closures, without other improvements in a corridor, will typically result in increased user costs and the analysis accounts for these offsetting impacts.

The costs in *GradeDec.Net* are the costs to operate and maintain crossings and the capital outlays for improvements (investment).
Grade Crossing Investments

A grade crossing investment is a one-time, capital outlay or set of measures that transforms grade crossings in a corridor or region in any of the following ways.

- **Grade crossing device type change.** Where "types" are passive, lights, gates, "new technology" and, as well, closure or grade separation.

- **Additions of supplementary measures to gated crossings.** These supplementary measures include: four quadrant gates without detection, four quadrant gates with detection, four quadrant gates with 60 feet medians, mountable curbs, barrier curbs, one-way streets, and photo enforcement.

- **Changes to highway traffic flows in a corridor** using traffic management measures like signage and signaling intended to re-assign traffic away from high-exposure/high-risk crossings during peak exposure periods of the day.

The device type, supplementary measures and traffic management measures at grade crossings determine in the analysis the predicted number of accidents and their severity. When proposed investments include grade crossing closures and separations, GradeDec.Net evaluates any additional re-allocation of traffic that is likely to occur.

The user has the option of a) allowing all investments at crossings to be implemented in the base year, or, b) developing a capital program by crossing in which one or two phases of improvements can be specified and a year of implementation for each phase (i.e., in year 3 upgrade crossing to gates and in year 15 grade separate the crossing).

This capital programming feature enables the use to develop and evaluate multi-year grade crossing improvement strategies that accommodate the anticipated growth in traffic and the availability of funding.

**Base Case and Alternate Case**

The Base Case represents the "no major investment" scenario. In the Base Case, the analysis evaluates the operational impacts and associated benefits and costs over the time horizon of the analysis with the minor improvements. An analysis will typically include a program of modest investments in the Base Case where these investments are part of a minimal fall back position that are most likely to be undertaken in lieu of the more extensive investments.

In the Alternate Case, the analysis evaluates the benefits and costs under the assumption that the proposed investments (in the designated years for cases with capital programming) have been implemented.

---

1. New technology is a placeholder type for any prospective new device or combination of devices. The user can specify up to three new technologies and set a parameter that determines the effectiveness of the new technology relative to a gated crossing.
In *GradeDec.Net* the following parameters are set for each of the two cases:

- Type of each grade crossing
- Supplementary measures at gated crossings
- AADT at crossings (which are the same for both cases unless the improvement program specifically includes traffic management measures for re-assigning traffic)
- Characteristics of rail operations at crossings
- O&M and other lifecycle costs
- Capital investment (alternate case only).

### Corridor or Region

*GradeDec.Net* evaluates a collection of grade crossings in a single analysis. The user must select whether to include the crossings for evaluation in a corridor or in a region. *GradeDec.Net* has a separate analytic model for corridors and for regions. The corridor model provides greater analytic depth than the regional model. The following features are available in the corridor model, but not in the regional model:

- Choice of high speed rail model or DOT model for accident prediction and severity,
- Re-assignment of highway traffic at grade separated or closed crossings,
- Estimation of benefits from a reduction in delay on the adjacent highway network.

If the crossings for evaluation lie on a single rail alignment, then the user should use the corridor model. On the other hand, if the candidate crossings for improvement span several alignments and are grouped in a region, then the user should use the regional model. *GradeDec.Net* is able to extract data directly from the National Grade Crossing Inventory database, or other external source, and import the data directly into a corridor or region.

### The Corridor

The rail corridor is a single, continuous alignment of one or more railroad tracks. The corridor may include up to 600 grade crossings that are candidates for improvement. The *GradeDec.Net* model characterizes the rail corridor by several parameters:

- The average daily number of trains by type (passenger, freight and switch) in the base year (see definition below).
- The time-of-day distribution of rail traffic (there are five pre-defined, time-of-day traffic distributions)
- A Boolean (yes/no) flag that specifies whether grade crossing closings are synchronized with the highway traffic signaling system in the corridor.

- Factors for up to three technology improvements. New technologies include non-conventional barriers and systems that provide timely notification to approaching trains of vehicle intrusion. Due to the absence of historical data on the performance of devices of these types, GradeDec.Net does not provide historically based estimates of new technology impacts. Values supplied for this factor represent the analyst’s best judgment regarding the likely impact of new technology relative to conventional flashing lights and gates closure. For instance, a value of 0.5 for this factor will reduce by half the accident risk relative to flashing lights and gates.

The corridor model analysis evaluates the impacts of closures and separations along the rail corridor. For closed crossings in the alternate case, the highway traffic from the crossing is re-allocated to adjacent crossings in the corridor. For grade separation improvements, the model estimates the attracted traffic to the grade separated crossing from adjacent crossings (see sections below on traffic re-assignment).

In addition to time savings benefits for highway vehicles at the crossing, the corridor model calculates the impact of reduced queuing at the crossings on highway network delays.

**The Region**

The regional analysis considers crossings in a geographic region: a county, several counties or any collection of crossings that may or may not be part of a common alignment. The regional analysis does not account for any re-assignment of highway traffic in the event of closure or separation. Because there is no accounting for re-allocated traffic if a crossing is closed, the analyst needs to specify a parameter in the crossing data entry that indicates the percent reduction in user costs for the closed crossing. See the discussion on this parameter ("percent benefits at closed crossing") in the data entry section.

Like a corridor, a region can include for analysis up to 600 grade crossings.

While a regional analysis provides less depth, the analyst can import most of the required data directly for a designated region from the National Grade Crossing Inventory Database (which is accessible from within GradeDec.Net).

**The Time Horizon**

The time horizon of a GradeDec.Net analysis is determined by the "start year" and "end year" values of the input scenario. The analysis assumes that all investments in the corridor are executed in "year 0" (the base year).
and that benefits accrue beginning in "year 1" (start year). For instance, if a scenario has start year 2014 and end year 2036 then the model assumes investments in the corridor have been completed by the end of 2013 (the base year) and are fully operational from the beginning of 2014. Benefits from the investment will accrue in the alternate case beginning in year 2014. The analysis assumes that benefits and costs are realized at year end. The "present value" calculation converts dollar values over the time horizon of the proposed investments to their equivalent dollar value at the beginning of the start year (i.e., benefits in the start year are discounted).

There are separate growth rate parameters in the model for the "near term" and the "far term". In many cases, planners face differing near-term and far-term growth outlooks. For instance, a region may have sound forecasts for near-term rapid growth yet may view these as unsustainable in the far-term. By allowing the user to split the time horizon into a near- and far-term while determining the duration of the near-term, GradeDec.Net accommodates a wide range of likely growth paths.

The user determines the near- and far-terms by specifying in the input scenario definition a year called "the last year of near term". The last year of near term is a year between the start year and end year. For instance, if the start year is 2014 and the last year is 2036, the last year of near term could be 2017. From the start year until and including the last year of near term, the model applies the near term growth rates for highway and rail traffic. From the year following the last year of near term and until the last year of the analysis, the model applies the far term growth rates.

**Costs and Prices**

The calculations of GradeDec.Net assume constant dollar values, and that relative prices - with the exception of fuel and oil - remain fixed over the time horizon of the investment. If all relative prices were fixed (i.e., if the ratio of the prices of any two goods or services did not change) then there would be no need to track prices in the model at all. Because the price of fuel and oil relative to other prices is allowed to vary, there is a need to track the general price level (inflation) and the level of the price of fuel and oil in order to calculate the constant dollar price of fuel and oil. Fuel (and oil) is singled out due to the volatility of fuel prices, and will likely fluctuate in comparison to other prices. In GradeDec.Net, if the price of fuel and oil increases faster than inflation, then the share of vehicle operating costs in total benefits will increase.

The "discount rate" is a constant dollar rate, that is, it is net of general price inflation.

---

**The GradeDec.Net Computational Model**

GradeDec.Net includes the following analytic components:
- Re-assignment of highway traffic due to closures and grade separation (corridor model only)
- Calculation of safety benefits through predicted accidents and severity in the base and alternate cases
- Calculation of other benefits from crossing improvements
- Present value and benefit-cost summary including consumer surplus calculation for the corridor or region

For the estimation of safety benefits GradeDec.Net employs one of two different computational models depending upon the user's selections. These are:

- **U.S. Department of Transportation (DOT) Accident Prediction and Severity Model (APS) and Resource Allocation Method**
- **Volpe National Transportation System Center (VNTSC) High-Speed Rail (HSR) Accident Severity Model**

When using the corridor model, the user can choose which of the two models to use. For the regional model, only the DOT APS model is available. Both models estimate predicted accidents by severity category for the base case and alternate case. The difference between the quantities of incidents is then monetized (i.e., multiplied by a unit cost per incident) and summed by grade crossing and year to arrive at annual safety benefits.

In the DOT APS the incident metrics are "fatal accidents" (accidents with at least one fatality), "injury accidents" (accidents with no fatalities and at least one injury), and "property damage only" accidents. The HSR model estimates fatalities and injuries for both the highway and rail modes while examining casualties for different types of accidents and their probabilities of occurrence.

The following sections describe how the two safety models are integrated with the modes of usage of GradeDec.Net.

**The DOT Accident Prediction and Severity Model (APS) and the Resource Allocation Method**

This model is described in the document *Summary of the DOT Rail-Highway Crossing Resource Allocation Procedure-Revisited*, Office of Safety, Federal Railroad Administration, June 1987, Report No. DOT/FRA/OS-87/05. The model includes three components: a formula for accident prediction, a formula for severity prediction and a model for resource allocation. The formulas for accident prediction and severity are based upon regression analyses of accidents and grade crossing characteristics. APS is applied in GradeDec.Net as described in the above document with one modification: GradeDec.Net corrects for the
correlation between time-of-day distribution between rail and highway traffic.

The DOT method for resource allocation estimates the safety at crossings after improvement by applying "effectiveness multipliers" to the base case APS model results. These multipliers were derived from separate analyses of grade crossings and improvements. GradeDec.Net uses the resource allocation method in the corridor model (when the DOT APS model is chosen and not the HSR model) only in cases where there is no re-assignment of highway traffic at a crossing due to closures or separation. When average annual daily traffic changes at a crossing from the base to alternate case due to re-assignment, then the DOT APS is reapplied to the improved crossing characteristics and the new level of highway traffic.

The DOT APS formulas and the resource allocation method are always used in the regional model, using the same correction as the corridor model for correlation of time-of-day traffic distribution on the rail and highway modes.

The VNTSC High Speed Rail Accident Severity Formulas

The HSR model is an optional feature of the corridor model in GradeDec.Net. The model used follows procedure described in Assessment of Risks for High Speed Rail Grade Crossings on the Empire Corridor, Mark Mironer and Michael Coltman, High Speed Ground Transportation Division, VNTSC, April 1998. This model uses the same accident prediction methodology as the DOT model, but has distinct accident severity formulas. The model is based on an analysis of grade crossing accidents while focusing on the accident types (train strikes vehicle, vehicle strikes train), the impact of severe derailment and fatalities among train as well as highway vehicle occupants.

Data and Data Organization in GradeDec.Net

This section provides a brief overview of data and their organization in GradeDec.Net. Data are organized into elements that correspond to their function in the model.

The four principal data elements are:

- Corridor or region data
- Grade crossing data
- Scenario (risk analysis) data
- Model parameter and default data
The corridor data include the corridor-level data covering base year rail operations, rail time-of-day traffic distribution, and a toggle designating whether there is grade crossing signal integration with the neighboring highway network. Corridor data also includes three technology parameters that represent the effectiveness of new technology at a crossing relative to a conventional gated crossing. The data for a region includes its description and technology parameter, while the rail characteristics are included in the crossing data.

The grade crossing data include the physical characteristics of the grade crossing, crossing type for base and alternate case, accident rates and cost data. Accident rates are stored with the crossing data for exposition purposes only. Predicted accidents are recalculated for each year of the evaluation when a simulation is run.

The scenario data include the policy variables and forecast values that are necessary for generating the forecast streams of benefits and costs. These data are organized into four data sets: rail operations, highway, social costs and price indexes.

The model parameter and default include technical coefficients for fuel burn and emission rates. They also contain the default data for capital costs, time-of-day traffic distributions and the model parameters for the high speed rail accident severity model. The user can edit and modify all of the data and parameters described in this section.
The Model

Introduction

This section presents the computational model that was discussed in the "Model Overview". For each model component, explanations and formulas are provided. The following section covers the data and data organization of *GradeDec.Net*.

Accident Prediction and Severity

The accident prediction and severity formulas in *GradeDec.Net* are based upon the two sources cited in the introduction. These equations are applied in accordance with the mode of usage (corridor or regional model). In the corridor model, the user can specify whether to use the HSR formulas or the DOT formulas. Moreover, in the corridor model the alternate case calculation of accident prediction and severity will depend upon whether grade crossing improvements in the corridor, through closures and/or separation, result in re-allocation of highway traffic among crossings. The procedure by which *GradeDec.Net* applies the different formulas is shown in the following figure.
The following sections describe the accident prediction and severity equations in GradeDec.Net.

**Forecast Highway and Rail Traffic**

*GradeDec.Net* forecasts average daily highway traffic, by vehicle type, and number of trains, by train type, at each crossing based on base year traffic and traffic rates of growth for the near and the far term.

The formula for the highway traffic forecast at a crossing is:

**Equation 1  Average Annual Daily Traffic (Highway) at Crossing**

\[
AADT_{\text{year}} = AADT_{\text{year } - 1} \times \left(1 + \frac{AADT_{\text{gr}}}{100}\right)
\]

\[
AADT_{\text{gr}} = \begin{cases} 
AADT_{\text{ntgr}} & \text{if } \text{year} \leq \text{lynt} \\
AADT_{\text{ftgr}} & \text{if } \text{year} > \text{lynt}
\end{cases}
\]

\[
AADT_{\text{year }, \text{type}} = \beta_{\text{type}} \times AADT_{\text{year}}
\]

where:

- year the current year of the analysis
- \(AADT_{\text{year}}\) average annual daily traffic in current year (all vehicle types)
AADT_{year-1} \quad \text{average annual daily traffic in previous year (all vehicle types)}

AADTgr \quad \text{annual growth rate of AADT, percent}

AADTntgr \quad \text{annual growth rate of AADT in near term, percent}

AADTftgr \quad \text{annual growth rate of AADT in far term, percent}

lynt \quad \text{last year of near term}

vtype \quad \text{vehicle type (i.e., auto, truck or bus)}

\beta_{vtype} \quad \text{share vehicle type of total highway traffic}

AADT_{year,vtype} \quad \text{average annual daily traffic in current year by vehicle type}

\textbf{Equation 2 Average Daily Trains at Crossing}

\[ TV_{year} = TV_{year-1} \cdot \left\{ 1 + \frac{TVgr}{100} \right\} \]

\[ TVgr = \begin{cases} TVntgr, & \text{if year} \leq lynt \\ TVftgr, & \text{if} \; \text{year} > lynt \end{cases} \]

\[ TV_{year, type} = TV_{year} \cdot \frac{\sum_{type} tvb_{type}}{tvb_{type}} \]

where:

\text{year} \quad \text{the current year of the analysis}

TV_{year} \quad \text{average daily trains in current year (all train types)}

TV_{year-1} \quad \text{average daily trains in previous year (all highway vehicle types)}

TVgr \quad \text{annual growth rate of average daily trains}

TVntgr \quad \text{annual growth rate of average annual daily trains in near term}

TVftgr \quad \text{annual growth rate of average annual daily trains in far term}

lynt \quad \text{last year of near term}

ttype \quad \text{train type (i.e., passenger, freight, switch)}

tvb_{type} \quad \text{trains in base year by type}

TV_{year, type} \quad \text{average daily trains in current year by type}

\textbf{Exposure and Time-of-Day Correlations}

The principal explanatory factor for predicting accidents at grade crossings is exposure. Exposure is the probability that a train and a highway vehicle will both arrive at a grade crossing at the same time, thus allowing for the possibility of an accident. Exposure, and the effects of grade crossings improvements, will vary significantly depending upon whether the time-of-day distributions of rail and highway traffic are
highly correlated (temporal match), or, are highly uncorrelated (temporal mismatch). As an extreme example, if all rail traffic was at night while all highway traffic was by day there would be no risk of accidents and no vehicles would ever stand waiting at a closed crossing.

The two safety models used in GradeDec.Net do not account for the correlation between the diurnal distributions of rail and highway traffic. GradeDec.Net incorporates a modification to correct for this and requires that the user specify the time-of-day traffic distribution for the rail corridor, or in the case of the regional model, the user specifies the rail traffic time-of-day distribution for each crossing. The user also specifies the time-of-day distribution of highway traffic at each crossing for each of three traffic segments: car, truck and bus.

The diurnal distributions in GradeDec.Net divide the daily traffic into twenty-four hourly periods. The user interface of GradeDec.Net lets the user select from among the twenty-one pre-set traffic distributions. Five of these are labeled: Uniform, Peak AM, Peak PM, Day Flat and Night Flat. These five distributions are stylized diurnal distributions that are not representative of a particular facility type or traffic pattern. The remaining sixteen are representative traffic distributions for a range of facility types in both urban and rural locales.

**Figure 2 Traffic Distribution Profiles**

The diurnal distributions provided in GradeDec.Net are for convenience, and the user can modify these values or create new distributions so as to more accurately correspond to time-of-day travel patterns in the corridor or region under consideration.

The degree of exposure is captured in the benefits evaluation by the exposure correlation factor that is given by the following equation:

**Equation 3 Time-of-Day Exposure Correlation Factor**

\[
EF = \frac{\sum_i \left( \sum_k \alpha_k a_{ik} \sum_j \beta_j b_{jk} \right)}{\text{Max} \left( \sum_i \sum_k (\alpha_k a_{ik})^2, \sum_i \sum_j (\beta_j b_{jk})^2 \right)}
\]
where:

- \( i \) an index designating the hour of the day
- \( j \) an index of highway vehicle type (auto, truck, bus)
- \( k \) an index of train types (passenger, freight, switch in the corridor model or through and switch in the regional model)
- \( a_{ik} \) the share of daily trains of train type \( k \) at the crossing in the \( i \)th time-of-day period
- \( b_{ij} \) the share of daily traffic of vehicle type \( j \) in the \( i \)th hour of the day
- \( \alpha_k \) the share of train type \( k \) of total trains
- \( \beta_j \) the share of vehicle type \( j \) in daily highway traffic

Note: \[ \sum_i a_{ik} = 1, \quad \sum_j b_{ij} = 1, \quad \sum_k a_k = 1, \quad \sum_j \beta_j = 1 \]

*GradeDec.Net* calculates the exposure correlation factor for each crossing and year of the evaluation.

*GradeDec.Net* integrates with the DOT Accident Prediction formula by calculating the daily exposure equivalent that would be realized if the time-of-day correlation of traffic at the grade crossing equaled the national average. That "national average" is the average correlation that is reflected in the sample that served as the basis for the estimation of parameters in the DOT model. *GradeDec.Net* calculates the exposure correlation factor for each crossing and year of the evaluation.

**Equation 4 Daily Exposure with Time-of-Day Correlation**

\[ \text{Exposure} = 1.35 \cdot \text{EF} \cdot \text{AADT}_{\text{year}} \cdot \text{TV}_{\text{year}} \]

where:

- Exposure base year daily exposure with time-of-day correlation, effective daily exposures
- \( \text{EF} \) time-of-day exposure correlation factor (see Equation 3 above)
- \( \text{AADT}_{\text{year}} \) average annual daily traffic on the highway at the crossing
- \( \text{TV}_{\text{year}} \) average daily trains at the crossing

The value 1.35 in the above equation means that if there was full time-of-day correlation between the rail and highway modes at the crossing, then there would 35 percent more exposure than if the correlation were equal to the national average\(^2\). *GradeDec.Net* calculates the daily exposure with time-of-day correlation for each crossing and year of the evaluation.

\(^2\) 35% is the opinion of a surveyed expert regarding this factor's likely value.
Predicted Number of Accidents

The predicted number of accidents at a crossing is based upon the DOT Accident Prediction and Severity formulas. The predicted number of accidents is calculated for each crossing in each year (for the base case and sometimes for both base and alternate cases – see Figure 1 above). Note that when using the DOT Accident Prediction and Severity model, the predicted number of accidents is normalized to account for the accident history at the crossing (N is the number of accidents at the crossing in the previous five years). However, when using the HSR model, the accident history is not included as part of the formula.

Equation 5 Predicted Number of Accidents at the Crossing

\[ T_0 = \frac{1}{0.05 + a} \]
\[ T_0 = \frac{(a \cdot T_0) + N}{T_0 + 5}, \text{ for DOT formulas} \]
\[ N_A = a \cdot \text{Adj}, \text{ for HSR formulas} \]

where:

\[ a = k \cdot EI \cdot DT \cdot MS \cdot MT \cdot HL \cdot HP \]

### Number of Accidents by Severity Category – DOT Formulas

The DOT Accident Severity formulas predict the number of fatal accidents (accidents with at least one fatality) and the number of casualty accidents (accidents with at least one fatality or injury). *GradeDec.Net* calculates the number of injury accidents (accidents with at least one injury, but no fatality) as the number of casualty accidents less the
number of fatal accidents. Property damage only accidents are calculated as predicted accidents less casualty accidents.

The numbers of accidents by severity category are calculated from the following equation:

**Equation 6 Predicted Number of Accidents at Crossing by Severity Category (DOT Formulas)**

\[
KF = 440 \cdot 0.9 \\
MS = ms^{-0.9981} \\
TT = (\text{thru} + 1)^{-0.0872} \\
TS = (\text{switch} + 1)^{0.0872} \\
UR = e^{0.3571 \cdot \text{urban}} \\
KC = 4.481 \\
MS_{CA} = ms^{-0.343} \\
TK = e^{0.1153 \cdot \text{tracks}} \\
UR_{CA} = e^{0.2960 \cdot \text{urban}} \\
FA = \frac{NA}{1 + KF \cdot MS \cdot TT \cdot TS \cdot UR} \\
CA = \frac{NA}{1 + KC \cdot MS_{CA} \cdot TK \cdot UR_{CA}} \\
IA = CA - FA \\
PA = NA - FA - IA
\]

where:

- **ms** maximum timetable train speed, miles per hour
- **thru** through trains per day
- **switch** switch trains per day
- **urban** if crossing is urban, Urban=1, else Urban=0
- **tracks** number of railroad tracks
- **NA** predicted number of accidents per year at the grade crossing
- **FA** predicted number of fatal accidents per year at the grade crossing
- **CA** predicted number of casualty accidents per year at the grade crossing
- **IA** predicted number of injury accidents per year at the grade crossing
- **PA** predicted number of PDO accidents per year at the grade crossing
Number of Accidents by Severity Category – HSR formulas

While the DOT formulas calculate the predicted accidents by severity, the high speed rail model calculates the predicted number of fatalities among highway vehicle and train occupants. GradeDec.Net calculates the number of injuries as a fixed ratio to the number of fatalities.

The following figure shows the calculation flow for the high-speed rail accident severity formulas. The following equations show the calculation of fatalities at grade crossing accidents based upon: accident type (train strikes vehicle or vehicle strikes train), vehicle type (auto, truck or truck trailer), and occupants by mode (rail or highway).

Figure 3 Accident Severity with High Speed Rail Formulas

Equation 7 Predicted fatalities by mode of occupancy for accident given train strikes highway vehicle (HSR)

\[
F_{tsv_{occ}} = \sum_{type} \left[ \alpha_{type} \cdot sp_{type} \cdot \sum_{type} \beta_{type} \cdot \left( \gamma_{type} \cdot s_{type,occ} \cdot P(sd) \cdot s_{type,occ} \right) \right]
\]

and,
$sp_{type} = \begin{cases} sp_{type} \cdot sp_{type} \leq sp_{\max} \\ sp_{\max} \cdot sp_{type} > sp_{\max} \end{cases}, \text{ for } occ = \text{Highway vehicle occupants}$

$sp_{type} = sp_{type}, \text{ for } occ = \text{Train occupants}$

**Equation 8 Predicted fatalities for accident given highway vehicle strikes train (HSR)**

$$F_{vst\_occ} = \sum_{type} \alpha_{type} \cdot \sum_{type} \beta_{vtype} \cdot \gamma_{atype\_vtype\_occ}$$

where:

- $F_{vst\_occ}$: predicted fatalities when train strikes vehicle, by occupancy mode
- $F_{vst\_occ}$: predicted fatalities when vehicle strikes train, by occupancy mode
- $occ$: occupancy mode of fatality (e.g., train occupants, highway vehicle occupants)
- $atype$: accident type (e.g., train strikes vehicle, vehicle strikes train)
- $vtype$: vehicle type (e.g., auto, truck, truck trailer)
- $ttype$: train type (passenger, freight, switch)
- $\gamma_{atype\_vtype\_occ}$: model coefficient by accident type, highway vehicle type and occupancy mode of casualties
- $\beta_{vtype}$: share of vehicle type in highway traffic
- $\alpha_{type}$: share of train type in total rail traffic
- $sp_{type}$: average train speed, for train type
- $sp_{\max}$: train speed of maximum impact on highway fatalities
- $P(sd)_{vtype}$: probability of severe derailment
- $sd$: added severity with severe derailment (model coefficient)

**Equation 9 Total Predicted Fatalities (HSR)**

$$F = P_{tsv} \cdot \sum_{occ} F_{tsv\_occ} + (1 - P_{tsv}) \cdot \sum_{occ} F_{vst\_occ}$$

where:

- $F$: total predicted fatalities
- $F_{tsv\_occ}$: predicted fatalities when train strikes vehicle, by occupancy mode
- $F_{vst\_occ}$: predicted fatalities when vehicle strikes train, by occupancy mode
- $P_{tsv}$: probability that accident is of type train strikes highway vehicle

**Equation 10 Total Predicted Injuries (HSR)**

$$I = u \cdot F$$

where:
I  total predicted injuries
F  total predicted fatalities
u  ratio of predicted injuries to fatalities

Effectiveness Multipliers

The DOT resource allocation method recommends that the following effectiveness multipliers be applied to predicted accidents in the base case in order to arrive at the estimate for safety risk at the grade crossing with the proposed improvements.

Note that in using the effectiveness multipliers, predicted accidents in the alternate case equal the base case predicted accidents times one minus the effectiveness multiplier.

If a device is upgraded to one of the new technology types, then the upgrade effectiveness factor is equal to 1 minus the “upgrade to gates” effectiveness factor, times 1 minus the corresponding technology effectiveness factor.

Supplementary Safety Measures

The “Rule for the Use of Locomotive Horns at Highway-Rail Crossings” seeks to require the sounding of a horn at every crossing and provides detailed provisions for the establishment of ”quiet zones” that are exempt from the requirement. As part of its provisions, the proposed rule allows for jurisdictions to add supplementary measures to crossings that have the equivalent effect on predicted accidents as the use of a locomotive horn. The rule incorporates a number of research findings that allow for the evaluation of estimated impacts from a range of improvements at grade crossings.

The table below shows the estimated effectiveness of supplementary measures at gated crossings (where the effectiveness rate is the rate of
reduction in the number of predicted accidents with the supplementary device as opposed to a gated crossing).

Supplementary measures are applied to gated crossings only. In the alternate case, if a crossing is upgraded from a non-gated crossing to a gated crossing with supplementary measures, then the two effectiveness multipliers are applied serially.

GradeDec.Net allows for the re-routing of highway traffic in the corridor via changes in signage and signals, which can be effective in directing traffic away from high-risk/high-exposure crossings in the corridor. If the user has entered data indicating changes in AADT by traffic segment or changes in the time-of-day distribution of traffic segments, these changes will be reflected in the calculations of exposure.

Delay and Time-in-Queue

Accurate estimates of the non-safety benefits due to grade crossing investments depend upon properly quantifying the time that highway vehicles spend queued behind closed gates (or, waiting for a train to pass at ungated crossings). While the time-in-queue measure is the basis for the non-safety benefits (incremental emissions and vehicle operating costs while idling), the measure of time savings benefit is best measured as a function of highway vehicle delay. Delay differs from time-in-queue because it captures the total time impact of a closure, including the time it takes for vehicles to return to regular traffic flow.
GradeDec.Net employs techniques from recent research\(^3\) that have remapped the conventional time-space queuing model into a graphical construct plotting the cumulative vehicles in queue against time. With some relatively unrestricted simplifying assumptions, time-in-queue is derived as a multiple of delay. Both highway delay and time in queue are readily calculated using easy-to-obtain data. The analysis framework is shown in the figure below.

The figure shows the blockage of highway traffic flow that occurs at a blocked grade crossing. Referring to the figure, at point L the blockage begins, it ends at point J and the queue begins to disperse, at point K the last vehicle joins the queue and at point M all the queued vehicles have resumed free flow speed.

Time is plotted on the x-axis and the y-axis shows the cumulative number of affected vehicles. Curve \(V(t)\) is the "virtual" graph of traffic in free flow. The curves \(B_1(t)\) and \(B_2(t)\) show the number of queued vehicles. \(D_2(t)\) shows the number of dispersed vehicles that have returned to free flow speed.

The following set of equations describes the calculation of delay and time-in-queue in GradeDec.Net.

The crossing blockage time is calculated from the train speed and the train length. The model calculates the average crossing block time as follows:

---

Figure 4 Analysis of Delay and Time-in-Queue

Equation 11 Average Crossing Closure Time (minutes)

\[
CBT_i = \frac{cl_i \cdot nc_i + el_i}{spd_i \cdot cf} + \frac{36}{60} + \sum_i \delta_i \cdot CBT_i
\]

\[
ACBT = \frac{\sum_i \delta_i}{\sum_i \delta_i}
\]

where:

- \(i\) index indicating the type of train: passenger, freight or switch
- \(CBT_i\) crossing block time for train of type \(i\), minutes
- \(cl_i\) average car length for train of type \(i\), feet
- \(nc_i\) average number of cars for train of type \(i\)
- \(el\) engine length (set at 50 feet)
- \(cf\) factor for converting mph to feet per minute, equal to 5280/60
- \(spd_i\) average speed at the crossing of train of type \(i\), mph
- \(\delta_i\) trains per day of type \(i\)
- \(ACBT\) average crossing block time, minutes

Time per train is calculated in minutes. 36 seconds are added to the time per train to account for the lead time of warning or closure prior to the
arrival of a train (the model assumes that the lead time applies to passive crossings also, i.e., 36 seconds prior to the arrival of a train, highway motorists will not venture a crossing).

The number of crossing blocks in each time-of-day period equals the number of trains in the period and is calculated as follows:

**Equation 12 Number of Blocks in Time-of-Day Period**

\[
blocks_{\text{per}} = \sum_{\text{trtype}} Tr_{\text{trtype}} \cdot trtod_{\text{trtype,per}}
\]

where:

- \( Tr_{\text{trtype}} \): average number of daily trains of type (passenger, freight, switch)
- \( trtod_{\text{trtype,per}} \): Share of average daily trains of type in time-of-day period

The arrival rate of vehicles is given by the following equation:

**Equation 13 Arrival Rate of Vehicles (vehicles per second per lane)**

\[
\lambda = \frac{\sum_{\alpha} \left( \text{veh}_{\alpha,\text{per}} \cdot PCE_{\alpha} \right)}{6 \cdot 3600 \cdot \text{lanes}}
\]

where:

- \( \text{veh}_{\alpha,\text{per}} \): number of vehicles in traffic segment \( \alpha \) in period
- \( PCE_{\alpha} \): Passenger car equivalent by traffic segment (1 for autos, 1.8 for trucks and 2.73 for busses)
- \( \text{lanes} \): number of highway lanes at the crossing
- \( 6 \): the number of hours in the period
- \( 3600 \): the number of seconds per hour

The number of vehicles that are affected by a crossing block is given by:

**Equation 14 Number of Affected Highway Vehicles per Block per Lane**

\[
N_k = \frac{\lambda \cdot \mu \cdot ACBT \cdot 60}{\mu - \lambda}
\]

where:

- \( \lambda \): arrival rate of vehicles, vehicles per second
- \( \mu \): dispersal rate of vehicles, vehicles per second (constant value of 0.5)
- \( ACBT \): average crossing block time in minutes

The total vehicle delay in the time-of-day period is given by:
Equation 15 Total Vehicle Delay per Period (vehicle-hours)

\[ w = N_K \cdot \left[ ACBT \cdot 60 + \left( \frac{1}{\mu} - \frac{1}{\lambda} \right) \cdot \left( \frac{N_k + 1}{2} \right) \right] \cdot \frac{lanes}{3600} \cdot \text{blocks per} \]

where:
\( \lambda \)  arrival rate of vehicles, vehicles per second
\( \mu \)  dispersal rate of vehicles, vehicles per second (constant value of 0.5)
ACBT  average crossing block time in minutes
\( N_K \)  the number of affected vehicles at closure
lanes  number of highway lanes
blocks_{per}  number of crossing blocks per period

The line \( B_1(t) \) in the above figure represents the back of the queue. Its slope is given by:

Equation 16 Slope of the Back-of-Queue Function

\[ z = \frac{\lambda \cdot v_f \cdot k_j}{v_f \cdot k_j - \lambda} \]

where:
\( \lambda \)  arrival rate of vehicles, vehicles per second
\( v_f \)  freeflow speed of highway vehicles (constant value of 45 mph converted to feet per second)
\( k_j \)  traffic density in vehicles per feet at speed 0 (set to constant 0.05)

The above equation was derived from the flow-density relationship.

The time-in-queue per time-of-day period is given by:

Equation 17 Time-in-queue per Time-of-Day Period (vehicle-hours)

\[ t_q = N_K \cdot \left[ ACBT \cdot 60 + \left( \frac{1}{\mu} - \frac{1}{z} \right) \cdot \left( \frac{N_k + 1}{2} \right) \right] \cdot \frac{lanes}{3600} \cdot \text{blocks per} \]

where:
\( z \)  slope of the back-of-queue function
\( \mu \)  dispersal rate of vehicles, vehicles per second (constant value of 0.5)
ACBT  average crossing closure time in minutes
\( N_K \)  the number of affected vehicles at closure
lanes  number of highway lanes
blocks_{per}  number of crossing blocks per period
GradeDec.Net allocates delay and time-in-queue to each of the three traffic segments (auto, truck, bus) according to the shares of each traffic segment in total traffic for the time-of-day period. Delay and time-in-queue are summed for each traffic segment over the four daily periods to arrive at average daily delay and time-in-queue (for each segment). These metrics are used in the calculation of non-safety benefits.

Delay and time-in-queue per traffic segment per time-of-day period is given by:

**Equation 18 Delay for Traffic Segment in Time-of-Day Period (vehicle-hours)**

\[ w_{\alpha} = w \cdot \frac{\sum_{\alpha} \text{veh}_{\alpha,\text{per}}}{\sum_{\alpha} \text{veh}_{\alpha,\text{per}}} \]

where:

- \( w \) total vehicle-hours delay in time-of-day period
- \( \text{veh}_{\alpha,\text{per}} \) number of vehicles of type \( \alpha \) (auto, truck, bus) in period

**Equation 19 Time-in-Queue for Traffic Segment in Time-of-Day Period (vehicle-hours)**

\[ t_{q\alpha} = t_{q} \cdot \frac{\sum_{\alpha} \text{veh}_{\alpha,\text{per}}}{\sum_{\alpha} \text{veh}_{\alpha,\text{per}}} \]

where:

- \( t_{q} \) total time-in-queue in time-of-day period (vehicle-seconds)
- \( \text{veh}_{\alpha,\text{per}} \) number of vehicles of type \( \alpha \) (auto, bus, truck) in period

The average daily delay for each traffic segment is the sum of the delay for the traffic segment in the four time-of-day periods. The average daily time-in-queue for each traffic segment is the sum in the four time-of-day periods.
Highway Traffic Re-Assignment (Corridor Model Only)

With the corridor model, GradeDec.Net re-assigns highway traffic at the grade crossing in two instances: 1) a grade crossing closure and, 2) a grade separation. The rationale for the re-assignment is that with closure forecast traffic will take alternate routes and will cross the rail lines at other points of crossing in the corridor in order to reach their destination. With grade separation, the grade-separated route will have less traffic impedance than it would have had without the improvement. Travelers will have a greater propensity to choose the route with less impedance and, therefore, some diversion of traffic to the grade-separated route is anticipated. Re-assignment of traffic at grade separated crossings is a feature that the user can turn on or off when running a simulation.

Highway traffic is re-assigned in GradeDec.Net model prior to the calculation of all benefit categories.

Grade Closures

The re-assigned AADT for the crossing adjacent below (i.e., lower milepost number) to the closed crossing is given by:

**Equation 20 Diversion from Closure to Lower Adjacent Crossing**

\[
\text{aadt}_{i-1} = \text{aadtb}_{i-1} + \text{aadt}_i \left[ 1 - \frac{\text{mp}_i - \text{mp}_{i+1}}{\text{mp}_{i+1} - \text{mp}_{i-1}} \right]
\]

where:

- \( \text{aadt}_{i-1} \) average annual daily traffic at the crossing adjacent and below the closure, after re-assignment
- \( \text{aadt}_i \) average annual daily traffic at the closed crossing before re-assignment
- \( \text{aadtb}_{i-1} \) average annual daily traffic at the crossing adjacent and below the closure, before re-assignment
- \( \text{mp}_i \) the milepost value of the \( i \)th crossing, the closed crossing from which traffic is diverted

The re-assigned AADT for the crossing adjacent above (i.e., higher milepost number) to the closed crossing is given by:

**Equation 21 Diversion from Closure to Upper Adjacent crossing**

\[
\text{aadt}_{i+1} = \text{aadtb}_{i+1} + \text{aadt}_i \left[ 1 - \frac{\text{mp}_{i+1} - \text{mp}_i}{\text{mp}_{i+1} - \text{mp}_{i-1}} \right]
\]

where:

- \( \text{aadt}_{i+1} \) AADT at the crossing adjacent and above the closure, after re-assignment
aadt, AADT at the closed crossing before re-assignment
aadt_{i+1}, AADT at the crossing adjacent and above the closure, before re-assignment
mp, the milepost value of the ith grade crossing

**Grade Separation**

After re-assigning traffic due to closures *GradeDec.Net* looks for grade separations and re-assigns traffic to account for the reduced traffic impedance at separated crossings. The model can be run without re-assigning traffic due to grade separations. On the simulation screen of the model, uncheck the box that says "Re-assign traffic if grade separated".

The potential AADT diverting from an adjacent crossing to a grade separated crossing is given by:

**Equation 22 Potential AADT Diverted from Adjacent Crossing to Grade Separated Crossing**

\[
pAADTd = \min PD + (\max PD - \min PD) \cdot \frac{1}{1 + e^{-(\alpha + \beta \cdot D)}}
\]

where:

- \( pAADTd \) percent of potential AADT diverting from the crossing due to a grade separation at an adjacent crossing (a function of the distance to the nearest major highway intersection)
- \( \min PD \) minimum percent of potential AADT diverting from the crossing due to a grade separation at an adjacent crossing (independent of the distance to the nearest highway intersection). This value is set to 5.
- \( \max PD \) maximum percent of potential AADT diverting from the crossing due to a grade separation at an adjacent crossing (independent of the distance to the nearest highway intersection). This value is set to 15.
- \( \alpha \) equation parameter set to 4.783. This parameter and the following one are set to meet two conditions: 1) if distance of crossing is .1 miles from closest major highway intersection then the value of F in the above equation is 0.99, and 2) if distance of crossing is 5 miles from closest major highway intersection then the value of F in the above equation is 0.01.
- \( \beta \) equation parameter set to -1.876 and meeting the conditions described above.
- \( D \) percent of potential AADT diverting from the crossing due to a grade separation at an adjacent crossing
Figure 5 Potential Diversion due to Grade Separation

![Graph showing potential diversion due to grade separation]

Equation 23 Percent AADT Diverted from Crossing to adjacent Grade Separated Crossing

\[ \text{percent of diversion of AADT} = p_{\text{AADT diverted}} = p_{\text{AADT diverted}} \cdot \left( 1 - \frac{\Delta MP}{\text{max } MP} \right)^{\gamma} \]

where:

- \( p_{\text{AADT diverted}} \) percent of diversion of AADT from the traffic at the crossing to the adjacent, grade separated crossing.
- \( p_{\text{AADT diverted}} \) percent of potential AADT diverting from the crossing due to a grade separation at an adjacent crossing (see above equation).
- \( \Delta MP \) distance between the adjacent crossing and the grade separated crossing.
- \( \text{max } MP \) the maximum distance between adjacent crossings, beyond which there is no diversion due to grade separation. This value is set to 10 miles in the model.
- \( \gamma \) an equation parameter reflecting the diminishing impact of grade separation on the route choice as the position of the adjacent crossing is further from the grade separated crossing. The parameter determines the concavity and the pace at which the impact diminishes with distance from grade separation. In the model and in below the parameter is set at 1.5.
The following sections describe the calculation of benefits and costs in GradeDec.Net.

**Safety Benefits**

The accident prediction and severity sections above describe the procedures for calculating predictions by severity type, with the DOT formulas, and fatalities and injuries, with the HSR formulas. GradeDec.Net calculates the safety benefits as:

**Equation 24 Safety Benefits (for each year and crossing – with DOT formulas)**

\[
SB = \sum_{i} (AccB_i - AccA_i) \cdot CPAcc_i,
\]

where:

- **SB** safety benefit, constant dollars
- **i** accident severity type (fatal, injury, PDO)
- **AccB_i** number of accidents in base case, type i
- **AccA_i** number of accidents in alternate case, type i
- **CPAcc_i** cost per accident, type I

**Equation 25 Safety Benefits (for each year and crossing – with HSR formulas)**

\[
SB = \sum_{i} [(CasB_i - CasA_i) \cdot CPCas_i] + (NAB - NAA) \cdot OPCacc
\]

where:

- **SB** safety benefit, constant dollars
i casualty severity type (fatal, injury)
CasB<sub>i</sub> number of accidents in base case, type i
CasA<sub>i</sub> number of accidents in alternate case, type i
CPCas<sub>i</sub> cost per casualty, type I
NAB predicted number of accident, base case
NAA predicted number accidents, alternate case
OPCAcc average out-of-pocket cost, dollars

**Travel Time Savings**

*GradeDec.Net* computes travel time benefits based on the delay experienced by the highway vehicles at the highway-rail grade crossings. See the section on delay for a complete discussion.

The model calculates the probability that an individual highway vehicle will be blocked at a highway-rail grade crossing and the minutes of delay per vehicle. The product of these two quantities provides the average delay that each highway vehicle endures. This quantity is then multiplied by the total number of highway vehicles that arrive at the blocked grade crossing to obtain the total vehicle hours of delay. The highway vehicle delay hours are divided into passenger vehicles and trucks based upon the percentage of trucks data entry for the crossing.

The delay per blocked vehicle is equal to the time per train converted to hours. The probability that a vehicle is blocked equals the total daily block time (time per train times number of trains per day) times the exposure correlation factor (a number between 0 and 1 representing the correlation between the time-of-day distributions of rail and highway traffic).

The vehicle hours of delay are calculated at each crossing and for each year of the evaluation.

**Equation 26 Time Savings Benefits (for each year and crossing)**

\[
P_{\text{VDC}} = \frac{w_{\text{auto}}}{60} \cdot \text{avgocc} \cdot \text{votpx} \\
T_{\text{DC}} = \frac{w_{\text{truck}}}{60} \cdot \text{votr} \\
B_{\text{DC}} = \frac{w_{\text{bus}}}{60} \cdot (\text{votr} + \text{avgoccbus}) \cdot \text{votpx} \\
D_{\text{CA}} = (P_{\text{VDC}} + T_{\text{DC}} + B_{\text{DC}}) \cdot AF \\
TTSB = D_{\text{CA}}_{\text{base}} - D_{\text{CA}}_{\text{alt}}
\]

where:

- PVDC average daily passenger vehicle delay time cost, dollars
- w<sub>auto</sub> average daily passenger vehicle delay, vehicle-minutes
avgocc  average passenger vehicle occupancy, passengers per vehicle
votpx  value of passenger time, dollars per hour
BDC    average daily bus delay time cost, dollars
$w_{bus}$  average daily bus delay, vehicle-minutes
vottr  value of truck time (driver time), dollars per hour
TDC    average daily truck delay time cost, dollars
$w_{truck}$  average daily truck delay, vehicle-minutes
DCA    annual delay costs, dollars
AF     annualization factor
TTSB   annual travel time savings benefit, dollars

**Environmental Benefits**

*GradeDec.Net* calculates the reduction in highway vehicle emissions due to reduced idle time at the grade crossings. There will be reduced emissions with grade separations and closures. However, the reductions in emissions at the closed crossing will typically be offset by increases in emissions at the crossings that absorb traffic diverted from the closed crossings.

There are emission rate tables for automobiles, transit vehicles, and trucks for three emission types: carbon monoxide, hydrocarbons, and nitrous oxide. The model uses these values to calculate emissions from idling vehicles at grade crossings. Emission costs for highway vehicles are calculated by multiplying the appropriate emission rate (by vehicle type) by the time spent by each vehicle type at the grade crossing. This calculation is performed for the base and alternate cases, the net difference being the change in vehicle emission.

**Equation 27 Average Daily Emissions at Crossing by Vehicle Type**

\[
EM_{E_{type}} = \sum_{V_{type}} ER_{V_{type}, E_{type}} \cdot t_{q V_{type}} \cdot \frac{60}{907185}
\]

where:

- $E_{type}$  emission type: HC, CO, NOx
- $V_{type}$  type of vehicle: car, truck or bus
- $ER_{V_{type}, E_{type}}$  emission rate (grams per minute)
- $t_{q V_{type}}$  time-in-queue by vehicle type, vehicle-hours
- $EM_{E_{type}}$  emissions by type (tons per day)

The value 907185 is the number of grams per ton.
**Equation 28 Environmental Benefits (for each year and crossing)**

\[ EB = \sum_{Etype} \left( \left( EM_{\text{Base}, Etype} - EM_{\text{Alt}, Etype}\right) \cdot VOE_{Etype} \right) \cdot AF \]

where:
- \( Etype \) emission type: HC, CO, NOx
- \( EM_{\text{Base}, Etype} \) emissions by type in base case, tons
- \( EM_{\text{Alt}, Etype} \) emissions by type in alternate case, tons
- \( VOE_{Etype} \) emissions cost, dollars per ton
- \( AF \) annualization factor
- \( EB \) environmental benefit, dollars

**Vehicle Operating Cost Savings**

*GradeDec.Net* computes the vehicle operating cost savings as a result of the improvements at the highway-rail grade crossing. Savings are generated from the reduction in delay at the grade crossing following the grade crossing upgrade. Between the base and alternate cases, a reduction in delay will lead to decreased consumption of fuel and oil by the vehicles operating on the highways. Vehicle consumption of fuel and oil is calculated for each vehicle type using the rates of idling consumption of fuel and oil. The time delay for each vehicle type is multiplied by the consumption rate to derive the fuel or oil consumed by the vehicles at the grade crossing.

Vehicle operating cost savings are then calculated by aggregating the change in gasoline, diesel and oil consumption for the different vehicle types and multiplying by their respective costs.

**Equation 29 Average Daily VOC at Crossing by Vehicle Type**

\[ FCI_{Ftype} = \sum_{Vtype} BR_{Vtype, Ftype} \cdot t_{q, Vtype} \cdot 60 \]

where:
- \( Ftype \) fuel or oil type: gasoline, diesel, oil
- \( Vtype \) passenger vehicles, buses, trucks
- \( BR_{Vtype, Ftype} \) fuel burn rate - gallons (gas and diesel) or quarts (oil) per minute
- \( t_{q, Vtype} \) time-in-queue by vehicle type, vehicle-hours
- \( FCI_{Ftype} \) fuel/oil consumed idling during delays, gallons (gas and diesel) or quarts (oil)
Equation 30 Vehicle Operating Cost Benefits (for each year and crossing)

\[
FCOST_{Ftype, year} = FCOST_{Ftype, year - 1} \cdot \frac{(1 + fpirg_{year})}{(1 + cpirg_{year})}
\]

\[
FCIC_{Ftype} = FCI_{Ftype} \cdot FCOST_{Ftype}
\]

\[
FCIC = \sum_{Ftype} FCIC_{Ftype} \cdot AF
\]

\[
VOCB = FCIC_{Base} - FCIC_{Ab}
\]

where:

- \( FCOST_{Ftype, year} \) the constant dollar price of fuel in forecast year
- \( fpirg_{year} \) the fuel price index rate of growth
- \( cpirg_{year} \) the general price rate of growth
- \( FCIC_{Ftype} \) fuel cost by fuel type
- \( FCI_{Ftype} \) average quantity of fuel consumed per day idling at crossing
- \( AF \) annualization factor
- \( VOCB \) vehicle operating cost benefit

**Network Benefits (Corridor Model Only)**

*GradeDec.Net* computes the estimated impacts of crossing investments on delay reduction on the neighboring highway network. The calculation relies on the average queue length on the approaching highway segments and the distance to the nearest major highway intersection.

The model assumes that network delay is negligible when the queue does not extend to within one-half the distance to the nearest highway. As the queue lengthens beyond the half-way, the network delay increases until it reaches a value of 10 vehicle-minutes at the point where the queue extends to the nearest highway crossing. The network delay will continue to increase at a declining rate as the queue length reaches and extends beyond the intersection. If the grade crossing signal is synchronized with the highway traffic signals, then network delay from the grade crossing is reduced by 50%. The calculation of network delay for each crossing in each year is as follows:
Equation 31 Network Delay (for crossing, year)

\[
VAPH = \frac{\sum_j \beta_j b_{j,per}}{6}
\]

\[
VAPB = VAPH \cdot \frac{ACBT}{60}
\]

\[
QL = \frac{vl \cdot VAPB}{5280 \cdot Lanes}
\]

\[
BPP = TV \cdot a_{per}
\]

\[
DQL = \begin{cases} 
QL - (dth - th), & \text{if } QL > (dth - th) \\
0, & \text{if } QL \leq (dth - th)
\end{cases}
\]

\[
ND_{per} = \begin{cases} 
\frac{A \cdot DQL^\beta \cdot BPP \cdot ndpq}{60}, & \text{if } sp \text{ false} \\
\frac{A \cdot DQL^\beta \cdot BPP \cdot ndpq \cdot 0.5}{60}, & \text{if } sp \text{ true}
\end{cases}
\]

\[
ND = \sum_{per} ND_{per}
\]

where:

ACBT average crossing block time, minutes (see Equation 11)

AADT average annual daily traffic at crossing

VAPH average number of vehicles arriving at crossing per hour in time-of-day period

\(b_{j,per}\) share of daily highway traffic of vehicle type \(j\) in time-of-day period

\(\beta_j\) share of vehicle type \(j\) in daily traffic

VAPB average number of vehicles arriving at crossing during block

QL queue length at blocked crossing, miles

vl average length of vehicle (set at 22 feet)

TV average number of trains per day

BPP average number of blocks per period

\(a_{per}\) share of daily trains in time-of-day period

DQL the portion of the queue length that contributes to network delay, miles

dth distance of crossing to nearest highway intersection, miles

th the distance from major intersection such that if queue extends beyond this point network delay begins to accrue. Set at half of dth.

ND\(_{Per}\) network delay in time-of-day period, vehicle-hours
A a value calibrated so that network delay equals 10 vehicle-minutes when queue reaches the intersection

β elasticity of network delay with respect to queue length, set to 0.7

sp true/false flag designating whether grade crossings are synchronized with signal progression on the highway network

ndpq the number of vehicle-hours of network delay caused by a queue extending to the nearest major intersection. Set at one-sixth vehicle-hours (equal to 10 vehicle-minutes)

ND daily network delay in vehicle-hours

Figure 7 Network Delay as a Function of Queue Length (when intersection is 0.5 miles from crossing)

As with the other benefits categories, network delay is calculated in the base and the alternate cases. The savings times the appropriate cost value is the network delay benefit.

Equation 32 Network Benefits (for each crossing and year)

\[
\begin{align*}
NDPC &= ND \cdot \left(1 - \text{strucks} \cdot \text{sbus}\right) \cdot \text{avgocc} \cdot \text{votpx} \\
NDBC &= ND \cdot \text{sbus} \cdot \left(\text{votr} + \text{avgoccbus} \cdot \text{votpx}\right) \\
NDTC &= ND \cdot \text{strucks} \cdot \text{votr} \\
NDCA &= (NDPC + NDBC + NDTC) \cdot AF \\
NDSB &= NDCA_{\text{base}} - NDCA_{\text{alt}}
\end{align*}
\]

where:

NDPC average daily cost of network delay, passenger vehicles, dollars

ND average daily network delay, vehicle-hours

avgocc average passenger vehicle occupancy, passengers per vehicle

votpx value of passenger time, dollars per hour

strucks share of highway traffic that is trucks

sbus share of highway traffic that is buses

NDBC average daily cost of network delay, buses, dollars
avgoccbus  average bus occupancy, passengers per bus
NDTC average daily cost of network delay, trucks, dollars
votr value of truck time, dollars per hour
NDCA annual network delay costs, dollars
AF annualization factor
NDSB annual network delay savings benefit, dollars

Local Benefits
Local benefits in the corridor are calculated as a percentage of the benefits from all the preceding benefits categories summed over all the grade crossings. These benefits represent the value of the grade crossing improvements to the local community or communities. These include benefits not conventionally counted like: improved mobility for residents (due to easier, safer crossings), reduced noise, economic benefits from improved access, etc. The local benefits are equal to the sum of all the previously discussed benefits times the local benefits factor.

Equation 33 Local benefits (for each year)

\[ LB = \left( \sum_{GCX} SB + \sum_{GCX} TTSB + \sum_{GCX} VOCB + \sum_{GCX} EB + \sum_{GCX} NDB \right) \cdot lbf \]

where:
LB Annual local benefits in the corridor, dollars
SB Annual safety benefits, dollars
TTSB Travel time savings benefits, dollars
VOCB Vehicle operating cost savings benefits, dollars
EB Environmental benefits, dollars
NDB Network delay savings benefits, dollars
lbf Local benefits factor (exogenously determined factor)

Project Costs
There are three components of project costs. First, there are capital outlays that are incurred in the alternative case. Second, annual operating and maintenance costs for each crossing. Third, other lifecycle costs for each of the grade crossings in the corridor. The following is the formula for costs:
Equation 34  Total and Net Project Costs (for each year)

\[
TC_{\text{Base}} = OM_{\text{Base}} + LC_{\text{Base}} + OM_{\text{ss Base}} + LC_{\text{ss Base}}
\]

\[
TC_{\text{Alt}} = \begin{cases} 
OM_{\text{Alt}} + LC_{\text{Alt}} + OM_{\text{ss Alt}} + LC_{\text{ss Alt}}, & \text{if } year > 1 \\
OM_{\text{Alt}} + LC_{\text{Alt}} + CC_{\text{Alt}} \cdot (1 + dr) + OM_{\text{ss Alt}} + LC_{\text{ss Alt}} + CC_{\text{ss Alt}} \cdot (1 + dr), & \text{if } year = 1 
\end{cases}
\]

\[
NC = TC_{\text{Alt}} - TC_{\text{Base}}
\]

where:

TC  total project costs in year (for each case, base and alternate), dollars

OM  operating and maintenance costs (for each case, base and alternate), dollars

LC  other life-cycle costs (for each case, base and alternate), dollars

CC  capital costs (alternate case only, presumed executed in year 0 - the base year), dollars

OMss  operating and maintenance costs (for each case, base and alternate) for supplementary safety measure (for gated crossings only), dollars

LCss  other life-cycle costs (for each case, base and alternate) for supplementary safety measure (for gated crossings only), dollars

CCss  capital costs (alternate case only, presumed executed in year 0 - the base year), for supplementary safety measure (for gated crossings only) dollars

dr  discount rate

NC  net project costs, dollars

Salvage Value

In an analysis of the benefits and costs of infrastructure investments, it is customary to “add back” the residual or salvage value of the investments at the end of the time horizon of the analysis. In principle, this represents the value of the remaining useful life of the capital improvements.

In GradeDec.Net the analysis assumes that the value of the invested capital declines by 5% per year. The salvage value is calculated at the end of the analysis period. In the benefit-cost summary it is discounted to present value terms.

\[
IVal_{invYr} = CapCost
\]

\[
IVal_i = IVal_{i-1} \cdot (1 - \delta)
\]

\[
Salvage = \sum_{\text{yr}} IVal_{\text{yr+1}}
\]

where:
\[ IVal_{\text{Invyr}} \quad \text{Value of the improvement in the year of its implementation} \]
\[ \text{CapCost} \quad \text{capital cost of the improvement} \]
\[ IVal_t \quad \text{Value of the improvement in year } t \]
\[ IVal_{t-1} \quad \text{Value of the improvement in year } t-1 \]
\[ \delta \quad \text{rate of depreciation, set at 5 percent per year} \]

**Consumer Surplus**

The benefit components described above include only the benefits accruing to current users of the roadway network. With grade crossing improvements, the generalized cost of travel by car in the corridor or region will decline. As a result, we expect that grade crossing improvements will induce some additional highway traffic. The consumer surplus includes both the consumer surplus from the base case auto trips as well as from the induced trips (see Figure 7 below). The model assumes that bus and truck traffic in the corridor or region are not sensitive to the changes in generalized cost from grade crossing improvements.

**Figure 8 Consumer Surplus**

In addition to incremental consumer surplus, induced trips will also generate external costs. GradeDec.Net calculates these external costs and deducts them from the total benefits. The following are the model
equations for the calculation of consumer surplus and the external costs from induced trips.

**Equation 35 Base Case Auto Travel Demand in the Corridor or Region**

\[ Q_n = \sum_i \alpha_i \cdot AADT_i \]

where:

i index of the crossing (i.e., each of n crossings in the corridor or region is indexed from 1 to n)

\( \alpha_i \) auto share of traffic at the crossing

AADT\_i average annual daily traffic at crossing i

The costs that influence the traveler's decision to make additional trips are the internal costs, namely: safety risk, travel time and vehicle operating cost.

**Equation 36 Base case Generalized Cost of Auto Trips**

\[ P_B = \frac{\sum_i (\alpha_i \cdot sr_{Bi} + tt_{Bi} + voc_{Bi})}{pTC / 100 \cdot Q_B} \]

where:

P\_B imputed average generalized trip cost in the corridor

\( \alpha_i \) auto share of traffic at the crossing

sr\_Bi auto cost of accidents at crossing i, dollars

tt\_Bi auto travel time delay costs at crossing i, dollars

voc\_Bi auto vehicle operating cost at crossing i, dollars

pTC percent share of trip costs at the crossing

Q\_B auto AADT at crossings in the corridor or region

*GradeDec.Net* represents highway auto travel demand with a standard, Cobb-Douglas functional form, which has a fixed elasticity of demand with respect to generalized cost.

**Equation 37 Auto Highway Travel Demand as a Function of Generalized Cost**

\[ Q = A \cdot P^\theta \]

where:

\( Q \) daily trips that traverse the crossings in the corridor or region as measured by AADT at the grade crossings

\( P \) the generalized average cost of auto trips traversing crossings in the region or corridor
The elasticity of demand for auto trips with respect to generalized cost is a constant, derived by substituting $Q_B$, $P_B$ and solving

$$\beta$$

The alternate case generalized cost is based on the imputed cost in the base case and the change in cost at the crossing.

**Equation 38 Alternate Case Generalized Cost of Auto Trips**

$$P_A = P_B + \left[ \sum_i (\alpha_i \cdot sr_{Ai} + tt_{Ai} + voc_{Ai}) - \sum_i (\alpha_i \cdot sr_{Bi} + tt_{Bi} + voc_{Bi}) \right] / Q_B$$

where:

- $P_B$: the imputed average generalized trip cost in the corridor in the base case
- $\alpha_i$: auto share of traffic at the crossing
- $sr_{Ai}$: cost of accidents at crossing, alternate case, dollars
- $tt_{Ai}$: travel time delay at crossing $i$, alternate case, dollars
- $voc_{Ai}$: the auto vehicle operating cost at crossing $i$, alternate case, dollars
- $sr_{Bi}$: the cost of accidents at crossing $i$, base case, dollars
- $tt_{Bi}$: travel time delay at crossing $i$, base case, dollars
- $voc_{Bi}$: the auto vehicle operating cost at crossing $i$, base case, dollars
- $Q_B$: auto AADT at crossings in the base case

The travel demand in the alternate case is derived by applying the auto travel demand function from **Equation 37**.

**Equation 39 Alternate case auto travel demand**

$$Q_A = AP_A^\beta$$

where:

- $P_A$: alternate case average generalized cost of travel in the corridor or region
- $\beta$: elasticity of auto travel demand with respect to generalized cost
- $A$: constant of demand function

Consumer surplus is estimated in the conventional way as the area beneath the demand curve. Since the demand curve is based on daily traffic, the result is annualized.

**Equation 40 Total Consumer Surplus (in each year)**

$$CS = A \int_{P_s}^{P_u} P^\beta dP \cdot AF = \frac{A}{1 + \beta} \left[ P_{s}^{\beta+1} - P_{u}^{\beta+1} \right] \cdot AF$$

where:
The consumer surplus from base case trips, and which is already included in the calculation of the benefit components, is given by:

**Equation 41 Consumer Surplus from Base Case Trips (in each year)**

\[ CS_1 = Q_B \cdot (P_B - P_A) \cdot AF \]

where:
- \( Q_B \) auto AADT at crossings in the base case
- \( P_B \) imputed average generalized trip cost in the corridor in the base case
- \( P_A \) imputed average generalized trip cost in the corridor in the alternate case
- \( AF \) annualization factor

The consumer surplus from the induced trips is the difference between the total consumer surplus and the consumer surplus from base case trips.

**Equation 42 Consumer Surplus from Induced Trips**

\[ CS_2 = CS - CS_1 \]

The disbenefit that is generated by induced trips is equal to the external costs (congestion and emissions) that each induced trip generates. This disbenefit is estimated by the following equation.

**Equation 43 Disbenefit from Induced Trips**

\[
\text{DisBen} = \left[ \sum_i (ec_{Ai} + ndc_{Ai}) \right] \left[ \frac{AF}{pTC / 100} \right] \left[ \frac{Q_A - Q_B}{Q_A} \right]
\]

where:
- \( ec_i \) emission costs at crossing \( i \), alternate case, dollars
- \( ndc_i \) network delay costs due to queuing at crossing \( i \), alternate case dollars
- \( pTC \) percent share of trip costs at the crossing
- \( Q_B \) auto AADT at crossings in the base case
- \( Q_A \) auto AADT at crossings in the alternate case
- \( AF \) annualization factor
Total Benefits and Benefit-Cost Indicators

GradeDec computes the corridor (or regional) level benefits from grade crossing improvements by aggregating the benefits estimated for each individual crossing and then adding the consumer surplus from induced trips and subtracting the disbenefit (in the form of external costs) from these trips. A simple sum is used to aggregate the safety benefits, travel time benefits, vehicle operating cost benefits, environmental benefits and network delay benefits.

**Equation 44 Total benefits (excluding local) in corridor (for each year)**

\[
TB = \sum_{GCX} SB + \sum_{GCX} TTSB + \sum_{GCX} VOCB + \sum_{GCX} EB + \sum_{GCX} NDB + CS_2 - DisBen + Salvage
\]

where:

- **TB** total annual local benefits in the corridor, dollars
- **SB** annual safety benefits, dollars
- **TTSB** travel time savings benefits, dollars
- **VOCB** vehicle operating cost savings benefits, dollars
- **EB** environmental benefits, dollars
- **NDB** network delay savings benefits, dollars
- **CS2** consumer surplus from induced trips
- **DisBen** disbenefit from induced trips
- **Salvage** Salvage value of investments (last year only)

The net benefits for the corridor or region are calculated as follows:

**Equation 45 Net benefits (excluding local) in corridor (for each year)**

\[
NB = TB - NC
\]

where:

- **NB** net benefits, dollars
- **TB** total benefits, dollars
- **NC** net project costs, dollars

The following formulas give the present value calculations of benefits, costs and net benefits.

**Equation 46 Present value benefits**

\[
PVB = \sum_{year} \frac{TB_{year}}{(1 + dr)^{year}}
\]
where:

\( P_{\text{VB}} \) present value of benefits, dollars

\( TB \) total benefits, dollars

\( dr \) discount rate

**Equation 47 Present Value Costs**

\[
P_{\text{VC}} = \sum_{\text{year}} \frac{N_{\text{C}}_{\text{year}}}{(1 + dr)^{\text{year}}}
\]

where:

\( P_{\text{VC}} \) present value of project costs, dollars

\( N_{\text{C}} \) net costs, dollars

\( dr \) discount rate

**Equation 48 Net Present Value**

\[
N_{\text{PV}} = P_{\text{VB}} - P_{\text{VC}}
\]

where:

\( N_{\text{B}} \) net present value, dollars

\( P_{\text{VB}} \) present value benefits, dollars

\( P_{\text{VC}} \) present value costs, dollars

The following is the benefit-cost ratio calculation.

**Equation 49 Benefit-Cost Ratio**

\[
B_{\text{CR}} = \frac{P_{\text{VB}}}{P_{\text{VC}}}
\]

where:

\( B_{\text{CR}} \) benefit-cost ratio

\( P_{\text{VB}} \) present value benefits, dollars

\( P_{\text{VC}} \) present value costs, dollars

The following is the project rate of return calculation.

**Equation 50 Project Rate of Return**

\[
P_{\text{RR}} = IRR \left( TB_{\text{year}} - N_{\text{C}}_{\text{year}} \right)
\]

where:

\( P_{\text{RR}} \) project rate of return

\( IRR \) designates a function that returns the discount rate for which the present value of the net benefit stream is equal to zero.

\( TB_{\text{year}} \) Total benefits, dollars

\( N_{\text{C}}_{\text{year}} \) Net project costs, dollars
Data and Data Organization

Introduction

There are four principal data elements in GradeDec.Net and these were described in the Model Overview section above. The following sections include detailed descriptions of the data in each of the data elements.

Corridor Data

The following are the corridor data variables. Except where noted, the variable descriptions are self-explanatory.

- **Number of Passenger Trains per Day**
- **Number of Freight Trains per Day**
- **Number of Switch Trains per Day**
- **Rail Traffic Daily Distribution**

The user can choose from one of five daily traffic distributions: uniform, AM peak, PM peak, day flat, night flat. These distributions of traffic divide the daily traffic into four six-hour periods. These are early AM (12AM-6AM), late AM (6AM-12PM), early PM (12PM-6PM), and late PM (6PM-12AM). The traffic distributions are each represented as a vector of four values that sum to 1. For example, the uniform distribution is given by (.25,.25,.25,.25). The GradeDec.Net default distributions are given in the "Time-of-Day Distributions" section of "Model Components". The user can modify these distributions to reflect conditions in the corridor under evaluation.

- **Signal Synchronization with the Highway Network (yes/no)**

This yes/no variable indicates whether the grade crossing signaling is synchronized with the signaling system of the adjacent highway network.

- **Technology Impact Factor**

The accident incidence of the "new technology" crossing type will be determined by the Technology Impact Factor. This factor determines the safety risk of new technology relative to conventional lights and gates.
crossing barriers, i.e., a value of 0.5 for this factor will yield safety risk half that of a lights and gates crossing.

## Region Data

Besides its description, the following are the two parameters associated with a region:

**Technology Impact Factor**

See the description above under Corridor Data.

**Percent Benefit from Closure**

The regional model, unlike the corridor model, does not reassign traffic at the crossing when the crossing is closed. When a crossing is closed, there are no longer highway user costs at the crossing. However, the trips of highway users who used the route with the crossing in the base case did not simply disappear. Most likely, the highway trips at the crossing will divert to another crossing and new user costs will be realized at that crossing. This "percent benefits" parameter determines the percent of base case user costs that will be realized as a benefit. For instance, if the parameter is set to 0 this is equivalent to all highway users finding alternate routes that have exactly the same user costs as the base case. If this parameter is set to a value greater than 0 (say, 10) this implies that users find lower cost alternatives in the alternate case when the crossing is closed and 10 percent of the base case cost is realized as benefit. Conversely, if the parameter is set to –10 then users find alternatives that are 10% more costly than the base case and there is a net disbenefit from the closure.

## Grade Crossing Data

The following are the crossing data variables. The variables noted below are either common to both corridors and regions, or are unique to one or the other as noted. Except where noted, the variable descriptions are self-explanatory.

**Milepost (corridor and region)**

The Milepost is a decimal number (i.e., 153.7) that identifies the crossing and specifies its geographic location within the rail corridor. The difference between the mileposts of two consecutive crossings should equal the distance between them in miles. The data for crossings in a corridor should be entered in a linear sequence (i.e., with mileposts in either ascending or descending order). This order has no significance for a region and the milepost only serves as an additional identifier of the crossing.

**Crossing ID (region only)**
This is the unique crossing ID corresponding to the 7-character crossing identifier in the National Inventory of Grade Crossings.

**Paved/Unpaved (corridor and region)**
This yes/no variable designates whether the highway at the crossing is paved or unpaved.

**Urban/Rural (corridor and region)**
A yes/no variable that designates whether the crossing is in an urban or rural

**Grade Crossing Base Type (corridor and region)**
This variable designates the type of crossing in the base case.
There are six types of grade crossings used in GradeDec.Net: passive, flashing lights only, flashing lights and gates, closure, grade separation and new technology. The "new technology" type of grade crossing is a hypothetical type of crossing that may involve advanced traffic management and information systems and/or new kinds of barriers.

The crossing types correspond to the crossing types in the National Inventory of Grade Crossings database. GradeDec.Net maps these types into the types used by its model as follows:

**Table 4 Mapping of Crossing Types**

<table>
<thead>
<tr>
<th>National Inventory Crossing Type</th>
<th>GradeDec.Net Crossing Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>No Device</td>
<td>Passive</td>
</tr>
<tr>
<td>Stand Stop Crossbuck Special Procedure</td>
<td></td>
</tr>
<tr>
<td>Flashing Lights</td>
<td>Flashing Lights</td>
</tr>
<tr>
<td>Wigwags Gates</td>
<td>Lights and Gates</td>
</tr>
</tbody>
</table>

Region crossing types also include closure, grade separation and new technology. These are the same types as in the corridor model.

**Grade Crossing Alternate Type (corridor and region)**
This variable designates the type of crossings in the alternate case. See the descriptions for crossing types in the base case.

**Safety Supplement Base Type (corridor and region, only available for gated crossings)**
This variable specifies whether a supplementary safety measure is deployed at the crossing in the base case. Supplementary safety measures include the following: four quadrant gates – no detection, four quadrant
gates with detection, four quadrant gates with 60 foot medians, mountable curbs, barrier curbs, one-way streets, and, photo enforcement.

**Safety Supplement Base Type (corridor and region, only available for gated crossings)**

This variable specifies whether a supplementary safety measure is deployed at the crossing in the base case. Supplementary safety measures include the following: four quadrant gates – no detection, four quadrant gates with detection, four quadrant gates with 60 foot medians, mountable curbs, barrier curbs, one-way streets, and, photo enforcement.

**Safety Supplement Alternates Type (corridor and region, only available for gated crossings)**

This variable specifies whether a supplementary safety measure is deployed at the crossing in the alternate case. See the Base Type description above.

**Number of Highway Lanes (corridor and region)**

**Highway Traffic (AADT) (corridor and region)**

This is the bi-directional average annual daily highway traffic at the crossing.

**Of the Highway Traffic, the Percent of Vehicles that are Trucks (corridor and region)**

**Of Trucks, the Percent that are Truck Trailers (corridor)**

**Of the Highway Traffic, the Percent of Vehicles that are Buses (corridor and region)**

**Auto Time-of-Day Traffic Distribution (corridor and region)**

This variable represents the distribution of auto traffic at the crossing in a typical 24-hour period.

The user can choose from one of five daily traffic distributions: uniform, AM peak, PM peak, day flat, night flat. These distributions of traffic divide the daily traffic into four six-hour periods. These are early AM (12AM-6AM), late AM (6AM-12PM), early PM (12PM-6PM), and late PM (6PM-12AM). The traffic distributions are each represented as a vector of four values that sum to 1. For example, the uniform distribution is given by (.25,.25,.25,.25). The **GradeDec.Net** default distributions are given in the "Exposure and Correlation of Time-of-Day Distributions by Highway and Rail" subsection of "The Model" section. The user can modify these distributions to reflect conditions in the corridor or region under evaluation.

**Truck Time-of-Day Traffic Distribution (corridor and region)**

This variable represents the distribution of truck traffic at the crossing in a typical 24-hour period. See the discussion under auto time-of-day traffic distribution.
**Bus Time-of-Day Traffic Distribution (corridor and region)**

This variable represents the distribution of bus traffic at the crossing in a typical 24-hour period. See the discussion under auto time-of-day traffic distribution.

**Yes/No Flag Indicating whether Alternate Case includes Traffic Management Measures for Re-assigning Traffic at the Crossing (corridor and region)**

This flag determines that the user specifies alternate case values for AADT by traffic segment and the time-of-day distribution of traffic segments. These new values represent the projected impact of proposed traffic management measure on highway traffic at the crossing.

**Highway Traffic (AADT), Of the Highway Traffic, the Percent of Vehicles that are Trucks, Of the Highway Traffic, the Percent of Vehicles that are Buses, Auto Time-of-Day Traffic Distribution, Truck Time-of-Day Traffic Distribution, Bus Time-of-Day Traffic Distribution – Alternate Case (corridor and region)**

These data are entered in the Alternate Case only if the flag indicating the presence of traffic management measures is set.

**Number of Railroad Tracks (corridor)**

This is the number of traffic-bearing tracks at the crossing.

**Number of Main Railroad Tracks (region)**

This is the number of daily traffic-bearing tracks at the crossing.

**Number of Other Railroad Tracks (region)**

Other tracks at the crossing are special use tracks.

**Maximum Schedule Train Speed (corridor and region)**

**Average Number of Day Through Trains (region)**

This includes both passenger and freight trains.

**Average Number of Night Through Trains (region)**

This includes both passenger and freight trains.

**Average Number of Day Switch Trains (region)**

**Average Number of Night Switch Trains (region)**

**Distance from Highway (corridor only)**

This is the distance, measured in miles, from the crossing to the nearest major highway intersection.

**Number of Accidents at Crossing in Past Five Years**

**Crossing Costs**

The cost data for the crossing include O&M costs and other lifecycle costs for the base and alternate cases and capital costs for the alternate
O&M and other lifecycle costs are annual outlays that are repeated every year. Capital costs (i.e. the cost of improving the crossing) is a one-time outlay that is expended in the year prior to the start year of the analysis.

**Scenario Data**

The scenario data include those variables to which probability distributions can be assigned. There are distinct scenarios for the two models, as the set of variables for the corridor model differs slightly from that of the regional model. In the descriptions below, the variables belonging to each model are shown.

A simulation engine solves the GradeDec.Net model for a specified number of trials. For each trial, a randomly sampled value is selected from each of the probability distributions as its input value. The collection of model solutions represents a probability distribution of the model's result variables.

The scenario variables are divided into four data sets, namely: Rail Operations, Highway, Social Costs and Price Indexes. For each of the variables in the scenario data the user can specify whether the value is fixed or, is one of four types of probability distributions. These distributions types are:

- uniform probability distribution, which requires the specification of two end points of an interval to define the distribution.
- normal probability distribution, which requires that the user specify the mean value and the standard deviation of the distribution, and
- a skewed-bell distribution that is normal when symmetric, but allows for skew and which requires three defining points corresponding to its 10, 50 and 90 percentiles.
- A triangle distribution, where the user specifies a minimum value, maximum value and the most likely value.

**Rail Operations**

These variables are used to define the rail operations in the corridor. The variables are:

- Annual Rate of Growth in Train Traffic, Near Term, Percent (corridor and region)
- Annual Rate of Growth in Train Traffic, Far Term, Percent (corridor and region)
- Number of Rail Cars per Freight Train (corridor)
Number of Rail Cars per Passenger Train (corridor)
Number of Rail Cars per Switch Train (corridor and region)
Average Length of Freight Rail Cars, Feet (corridor)
Average Length of Passenger Rail Cars, Feet (corridor)
Average Length of Switch Train Cars, Feet (corridor and region)
Number of Rail Cars per Through Train (region)
Average Length of Through Train Rail Cars, Feet (region)

Highway
The following variables define the corridor-level highway characteristics. The highway data are required for the forecasting of highway-related benefits.

Annual Rate of Growth of Highway Traffic, Near Term, Percent (corridor and region)
Annual Rate of Growth of Highway Traffic, Far Term, Percent (corridor and region)
Annualization Factor (corridor and region)
This is a factor for converting daily benefits to annual benefits.
Average Auto Vehicle Occupancy (corridor and region)
This is the average number of occupants per vehicle.
Average Bus Vehicle Occupancy (corridor and region)
This is the average number of passenger occupants on a bus.
Elasticity of Auto Travel Demand with respect to Generalized Cost of Travel (corridor and region)
This variable is the percent change in corridor or region AADT per percent change in generalized cost. For instance, if a 10% increase in travel cost results in a 1% decrease in AADT then the elasticity of demand with respect to cost is \(-0.1\). Many travel demand studies show that the value for the variable is many cases about \(-0.1\). The "generalized cost of travel" includes all of the internal costs of auto travel that are perceived by users including: vehicle operating costs, travel time and safety risk.
Average Percent of Auto Trip Costs that are Crossing-Related, Percent
This is the corridor or region average of the percent of total trip costs at the crossing. For instance, if an average trip has a generalized cost of $8.00 and $0.80 are the average trips costs at the crossing, then the value for this variable should be 10. This factor is used in the consumer surplus calculation.
Social and Other Costs

The variables represent the monetized value of social costs and the market value of other costs.

*The Discount Rate*

This variable is the real discount rate for the analysis. This rate is applied to future constant dollar cost and benefit streams (i.e., the benefits and costs have been adjusted to account for forecast inflation).

*Cost of a Fatal Accident, $'000 (corridor and region)*

*Cost of an Injury Accident, $'000 (corridor and region)*

*Cost of a Property Damage Accident, $'000 (corridor and region)*

*Cost per Fatality, $'000 (HSR formulas)*

*Cost per Injury, $'000 (HSR formulas)*

*Average Out-of-Pocket Cost per Accident, $''000 (HSR formulas)*

*Value of Time (auto) ($/person-hr.)*

*Value of Time (truck – driver time)) ($/truck-hr.) (corridor and region)*

*Cost of HC Emissions, $'000/Ton*

*Cost of NOx Emissions, $'000/Ton*

*Cost of CO Emissions, $'000/ Ton*

*Base Fuel Cost, $/Gallon*

This variable refers to the cost of fuel (dollars per gallon) in the base year.

*Base Oil Cost, $/Quart*

*Fuel Cost, Annual Rate of Change, Percent*

*Inflation, Annual Rate, Percent*

This variable refers to the cost of motor oil (dollars per quart) in the base year.

Sources for social cost default data included in the scenarios provided with GradeDec.Net for the values of time, crash costs and emissions costs were derived from:

---

**Model Parameters and Default Values**

The following parameters and default values are used in the model to calculate: accident costs, capital and maintenance costs, emission rates.
by vehicle type, railroad emissions by engine type, and the rate fuel and oil are consumed by vehicle type per minute.

Grade crossing types used in the following data tables are:

1. Passive Grade Crossing
2. Flashing Lights
3. Flashing Lights and Gates
4. Grade Closure
5. Grade Separation
6. New Technology

benefit-cost ratio 49

capital costs 14, 43, 55
closure 8, 10, 26, 28, 30, 32, 33, 52, 53
corridor 3, 4, 5, 7, 8, 9, 10, 12, 13, 14, 15, 18, 19, 26, 32, 42, 44, 45, 46, 47, 48, 51, 52, 53, 54, 55, 56, 57, 58
corridor model 5, 9, 10, 12, 13, 15, 19, 32, 52, 53, 56

default values 5, 58
demand 45, 46, 47, 57
device 8, 25, 26
discount rate 11, 43, 49, 58
discounting 3
distributions 4, 5, 17, 18, 36, 51, 54, 56

economic 3, 42
elasticity 41, 45, 46, 47, 57
emissions 3, 7, 26, 37, 38, 47, 59

F
facility type 18
FRA 3, 12, 59, 60
freeflow speed 30

gates 8, 10, 25, 26, 51, 53, 54, 59
grade crossing 3, 4, 5, 7, 8, 9, 10, 12, 13, 14, 15, 17, 19, 21, 22, 23, 25, 26, 27, 32, 33, 36, 37, 38, 39, 41, 42, 44, 45, 48, 51, 53
grade separation 8, 10, 12, 32, 33, 34, 37, 53

H
high speed rail 4, 9, 14, 23
HSR 12, 13, 15, 20, 23, 24, 35, 58

I
intersection 33, 39, 40, 41, 55

L
lanes 21, 29, 30
last year 11, 17, 48
lifecycle costs 9, 42, 55

N
net present value 49
normal 56

O
operating and maintenance costs 42, 43

P
parameters 9, 11, 14, 19, 52, 58
period of analysis 5
base year 8, 9, 10, 14, 16, 17, 19, 43, 58
end year 10, 11
Present Value 49
rate of return 3, 5, 49
region 3, 4, 7, 8, 9, 10, 11, 12, 13, 14, 18, 44, 45, 46, 47, 48, 52, 53, 54, 55, 56, 57, 58
regional model 5, 9, 12, 13, 15, 18, 19, 52, 56
risk analysis 4, 7, 13
trial 56

safety 3, 5, 7, 12, 13, 18, 25, 26, 31, 35, 42, 43, 45, 48, 51, 53, 54, 57
scenario 8, 10, 11, 14, 56
Signal 14, 39, 41
Simulation 14, 32, 33, 56
social costs 14, 58
start year 10, 11, 56

traffic distributions 9, 14, 18, 51, 54
traffic management measure 8, 9, 55
tavel time 7, 36, 37, 45, 46, 48, 57
triangle 56

uniform 18, 51, 54, 56
user costs 7, 10, 52

vehicle operating costs 3, 7, 11, 26, 57
