TASK 5 REPORT

1. EVALUATOR PROJECT OVERVIEW

The effort on this project was divided into three phases. The purpose of Phase I was to investigate several railroad accidents that were attributed to poor train handling. The results of this investigation were used to establish a potentially difficult train handling scenario to be utilized on the Evaluator. In Phase II a 35mm motion picture film that closely approximates the accident scenario developed in Phase I was procured, and track geometry and audio cues data bases that relate to the film were generated. The purpose of Phase III was to map a "core film" of approximately $1\frac{1}{2}$ hours to be used on the Evaluator.

1.1. Investigation

The railroad accidents studied were selected from those investigated by the National Transportation Safety Board (NTSB). The specific accident dockets chosen were those in which the NTSB's concluded that poor train handling was "a contributing factor to the severity of the accident."

Using NTSB quarterly Railroad Accident Report Briefs, approximately 15 railroad accidents that met the above criteria were selected. Ten of the fifteen accident dockets were acquired. Nine of the railroad accidents occurred in 1979 and the remaining one in 1978.

The names and locations of the accidents are listed in Table 1. The pertinent train handling information for each accident is shown in Table 2. Data depicted in Table 2 can be divided into the following categories: pertinent track geometry parameters (grade and curvature), train make up, engineers' use of his train and locomotive brakes, and the weather conditions at the accident site.

*Refer to Table 1 for Accident Identification.

It is apparent from the review of the accident reports that in 80 percent of the train handling accidents surveyed, the terrain consisting of descending grades greater than 1 percent and curvature exceeding 2 degrees were major contributing causes. In 50 percent of the accidents investigated, train engineers had recently made adjustments to their train and or locomotive brakes; suggesting that brake adjustments are critical. The Track Train Dynamics Study (TTDS) confirms that poorly planned applications of locomotive or train brakes while operating in undulating territory can produce high in-train forces, which can cause lading damage or equipment derailments. Both the TTDS and the results shown in Table 2 confirm that operating a train on descending grades greater than 1 percent can produce difficult train handling situations. Therefore, combinations of grades greater than 1 percent and curvatures greater than 2 degrees will produce difficult train handling situations.

When locomotive engineer's statements concerning their perceptions and reactions just prior to and during emergency brake applications are evaluated, it is typically found that these engineers thought they had their trains under control. Therefore, they did not take any corrective action to attempt to minimize in-train forces. This is an example of the short time period for slack action within the train to create large longitudinal forces that ultimately could cause segments of the train to derail. This also exemplifies the long time period it takes for this slack action to travel to the locomotive where the engineer can feel the run in.

When engineers operate their trains on undulating grades with multiple curves and do not maintain speed control, it may become increasingly difficult for them to regain control. In fact, the TTDS emphasizes the difficulty engineers have in attempting to regain speed control of the train once large longitudinal oscillations begin to develop within the train. In these cases, the TTDS recommends that the engineer stop as soon as possible. This recommendation is interesting because, in most

derailments, the engineer usually has not perceived that he has lost control until he hears the air discharging from the locomotive brake pipe, signifying an emergency brake application. At this time, it is too late for the engineer to take any corrective action.

The overall review of the data in Table 2 clearly supports the findings of the TTDS. Table 2 also shows that trains operating in the hours of darkness in territories consisting of varying grades and curvatures further compound the overall difficulties of train handling.

1.2 Conclusion

Train handling difficulties are greatly magnified when the terrain that must be traversed consists of undulating grades or descending grades that exceed 1 percent in concert with varying curves that exceed 2 degrees. In addition, the length and the make-up of trains are important. Poor train make-up usually affects the longitudinal stability of the train, especially for long trains, and this instability can produce large in-train forces. These uncontrolled forces can develop into a difficult train handling situation that could possibly be beyond the capabilities of many experienced engineers.

As a result of the Phase I survey and the TTDS, a potentially difficult train handling scenario to be implemented for the Evaluator must include undulating grades greater than 1 percent in conjunction with curves greater than 2 degrees.

2. DEVELOPMENT OF ACCIDENT SCENARIO

Film selection for the difficult train handling scenario for the Evaluator is crucial because the film provides to the engineer trainee visual information with respect to motion, track features and obstacles, signal aspects, and background scenery. To portray (to the engineer trainee) a realistic picture on the screen, the film should provide continuity of background scenery. Therefore, it is desirable to select continuous film

footage that would approximate one of the difficult train handling accidents that were surveyed as part of Phase I. If continuous film footage cannot be located then a film library must be developed. This film library should include short segments of film footage of each type of track, i.e., turns in both directions and of varying curvatures, tangent track sections, and possibly sections of track where changes in grade can easily be discerned.

The film library concept requires two duplicate films. The films would be mounted on the two separate projectors used for the Evaluator. This would allow film editing of the track section library by simply switching between the two synchronized projectors. The synchronization of the motion picture projectors on the Evaluator will be under computer control. The film sequences will be selected prior to beginning the experiment. This permits the computer to position the off-line projector to the appropriate film frame. When the two projectors are synchronized frame for frame, the computer will then transfer control to the projector that has the next film sequence.

3. FILM SELECTION

Copies of Southern Pacific's Pine Bluff 35mm films have been acquired. This film was produced for use on a train simulator located in their Engineer Training Center in Cerritos, CA. The film is their latest production and portrays over 60 miles of trackage photographed on their Cotton Belt Line in Arkansas. This film has been reviewed to evaluate its compatibility for use with the Evaluator. The film quality is excellent and the terrain covered has multiple scenes that have similar characteristics to the accidents portrayed in Table 2. The Pine Bluff films also have sections of continuous footage that closely approximate the multiple curves found at the Crestview, FL accident site that occurred on April 1979 on the Louisville & Nashville Railroad.

The actual grades of the SP films are not the same as those found at the Crestview accident. It appears that the grade data of this film can be adjusted to approximate closely the grade of the Crestview site, thus no serious problem exists in using the SP film. The grades found at the Crestview accident site varied between +/- 1 percent. The wavelength of these variations is on the order of 1 to 2 miles; therefore, the grade data base developed for the film can be adjusted to match closely the difficult grades found at the Crestview accident without creating any false grade cues to the operator of the Evaluator. It is anticipated that adjustments to the track geometry data base in curvature, cross level, and grade can be implemented without creating false cues.

4. DATA BASE DEVELOPMENT FOR CORE FILM

The Pine Bluff films acquired from SP had not been completely developed for use on their simulator; therefore, data bases for all track geometry parameters had to be extracted from different documents. Some of these documents had conflicting information. The majority of these conflicts were associated with the lengths of the different segments of a curve, i.e., lengths of entrance spirals, curve bodies, and exit spirals of several curves were not consistent. In most cases, these conflicts were not significant and trade-offs were made between conflicting information. The resulting data base is now consistent with all visual cues.

5. SOUTHERN PACIFIC DATA BASE

The photographing of the SP films were taken on their Cotton Belt Line in Arkansas. The camera used had a 25mm lens and exposed 20 picture frames/sec.

Nominal speeds for the camera train were 40 mph for the "A" film (core film) with one exception in the area of milepost 337 and 20 mph for alternate events on the "B" film.

SP recorded the speed of their camera platform vehicle in conjunction with camera frame signals. These signals were then processed to generate speed calibration data. This speed calibration data will be used to remove the effects of speed variation of the camera vehicle when the film is projected onto the motion picture screen for the Evaluator.

5.1 Milepost Data

The distances between mileposts along the track were taken from SP's profile charts, and this information is tabulated in Appendix A.

The number of picture frames between mileposts were taken from the track log shown in Appendix D. The ratio of picture frames to the distance between mileposts is the average number of frames per foot over the designated mile.

5.2 Grade and Elevation Data

Grade and elevation data was taken from SP's profile charts. These data are tabulated in Appendix B. Referring to Appendix B, the far left column is the position of the grade slope break point. The position is given as the number of feet from the last milepost; i.e., milepost 281 + 2 feet.

The data shown in the second column is the percent grade that will be traversed getting to the next grade break point. The third column is elevation data in feet above sea level found at the current grade breakpoint. The fourth column is the film frame number that depicts the location of the grade breakpoint.

5.3 Curvature and Crosslevel Data

The curvature data was taken from SP's profile and track charts; there are curves where these two charts were inconsistent. In these areas the data was manually adjusted to an acceptable value.

The crosslevel values were based on Superelevation and Speeds on Curves Table. A copy of this table is shown in Figure 1. Curvature and crosslevel data are tabulated in Appendix C.

<u>Degree of Curvature</u>	<u>Superelevation</u>	<u>Max Permissive Speed (MPH)</u>
30'	1"	81
1:00'	2"	80
1:30'	4"	79
2:00'	5 1/4"	75
2:30'	5 3/4"	68
3:00'	6"	64
3:30'	6"	60
4:00'	6"	56
4:30'	5 3/4"	52
5:00'	5 1/2"	48
5:30'	5 1/2"	45
6:00'	5"	43

FIGURE 1. EXCERPTS FROM SOUTHERN PACIFIC LINES COMMON STANDARD SUPERELEVATIONS AND SPEEDS ON CURVES

Referring to Appendix C, page 1, the column marked Curve Location indicates the location of the curve designated as 281.72. This notation will be used for curve locations in Appendices D, E, F, and G.

The line under the curve locator 281 + 3792 means that the beginning of the spiral of the curve is located 3,792 feet past milepost 281. The next column to the right indicates the curve is 1° to the left. The next column to the right is the crosslevel (super elevation) is 2", outside rail high. The last column indicates the film frame 1377 is where the spiral begins.

Likewise, the next line starts the curve body at a location 3,948 feet past MP 281 and film frame 1434 is where the curve body begins. Curve body ends and the trailing spiral begins at 4484 feet past MP 281. At this point the film frame number is 1630. The trailing spiral ends and the tangent track begins at 4,464 feet past MP 281. The film frame number at this point is 1687.

These data bases do not include rate of change of crosslevel and curvature in the entrance and exit spirals of a curve. A linear taper of these parameters over their respective distances should be adequate for the simulation program.

5.4 Core Film Map

The 35mm film footage provided by SP was viewed using a movieola. All pertinent data on the film was then mapped using the frame counter on the Movieola as a reference. With respect to milepost data there are two film frame numbers recorded. A negative frame number listed for a milepost sign indicates the last frame of film viewed on the movieola that had any portion of the milepost in it. Positive frame numbers listed for mileposts indicate the first frame of the film viewed on the movieola that has no visible portion of the milepost.

The camera optics and the film mapping techniques used for recording an events frame number as the events disappear from the

screen of the movieola create a problem in positioning the track geometry cues to the motion base of the Evaluator. To correct this, film frame numbers for events that are to be used as cues to the Evaluator's motion base are delayed approximately 32 ft. This delay in distance is necessary to allow the excitation of the Evaluator's motion base caused by the event to be synchronized with the lead wheels of the locomotive simulator.

5.4.1 Visual Cues

Visual cues are tabulated in Appendix E and they are a subset of the tabulated data in Appendix D. Engineers training on the Evaluator will use visual cues to determine when to activate the horn on the locomotive for road crossings, speed boards will be used to set train speed limits, wayside signals will be used for train control, and mileposts will be used for positional data.

5.4.2 Audio Cues

Audio cues are another subset of the tabulated data in Appendix D. These cues will be used to initiate sounds that are generated by objects on the tracks like switch points, frogs, ballast decked bridge, etc., and for noises associated with equipment located along the railroad right-of-way such as crossing signal bells, passing, standing or moving railroad vehicles on adjacent tracks, passing structures located close to the tracks, etc.

Audio cues are tabulated in Appendix F.

5.4.3 Motion Base Cues

Motion base cues are tabulated in Appendix G and are a subset of Appendix D.

Motion base cues are track features that would create vertical or lateral forcing functions to the wheels on a locomotive, thus causing the locomotive suspension system to

bounce, roll or yaw. Because these disturbances are a part of the locomotive traveling over different track features, these forcing functions are needed to realistically drive the motion base of the Evaluator.

With only one exception, the motion base parameters have been delayed in distance approximately 32 feet after the event disappears from the screen. The exception is the locations of entrance spirals, curve bodies, and exit spirals. The actual location of these features on the film are subjective and a correction of 32 feet would be insignificant and, furthermore, would have very little if any effect on the overall train simulation programs.

5.5 Film Calibration Data

Film calibration constants are tabulated in Appendix H. These data are printed whenever the speed constant has changed by more than \pm 2.5 percent. Referring to Appendix H, the first and third columns are film frame numbers and the second and fourth columns are camera vehicle velocities (feet/sec). To calculate the number of frames/foot for an example taken from film number 33 and its respective speed of the camera vehicle is found to be 59.78 f/s.

The number of film frames/foot(k) can be calculated by:

$$K = \frac{\text{camera frame rate}^*}{\text{camera vehicle speed}} = \frac{20}{59.78} = .3346 \frac{\text{frame}}{\text{foot}}$$

*Camera frame rate is 20 frame/sec.

Speed constant data is provided in Appendix H and on a nine track tape. The tape consists of one file of data which contains both the "A" and the "B" film data. The "A" data begins at record 0 and ends shortly after record 401g.* The "B" data begins at record 557g and ends at record 716g. Record length is 512 bytes which is equal to 256 16 bit words.

* 401g is 401 base 8 or 257 base 10.

The first record of each film's data contains four header words which are defined as follows:

- Word 0 - Distance between wheel pulses in feet scaled B3 (i.e., x xxx.xxx xxx xxx xxx). Thus the decimal value for film "A:" is 1.2788 ft.
- Word 1 - Most significant digits of starting frame
- Word 2 - Least significant digits of starting frame
- Word 3 - Spare

Speed data immediately follows the header words. Speed data consists of two word records for every 0.002 miles of film. The first word is the film frame number associated with that location and the second word is the speed constant (k) which represents the speed of the filming car at that location.

The dimensions of k are 'camera sync pulses/foot' \times 2048 (2 ** 11). There are 2.5 sync pulses/frame and there are 50 sync pulses/second; thus, conversion from sync pulses/foot to ft/sec or frames/ft is readily accomplished. For example, the formula for conversion to ft/sec is

$$V = (50) (2048)/k$$

Using this formula and the first k from the "A" film results in a train filming speed of 52.81 ft/sec or 36 mph.

5.5.1 Speed Limit

Along the track right-of-way are speed boards that display the maximum speed allowed on the track section. The speed limits may be lower than the posted speeds as viewed on the wayside "speed boards." A mechanism of implementing a lower speed limit is to use a Train Order.

The locations of each wayside speed board and its displayed speed limit are tabulated in Appendix I.

5.5.2 Train Makeup

The overall concept of this project is to reproduce a scenario similar to the Crestview, FL accident. Therefore, physical parameters for each rail vehicle involved in this accident are tabulated in Appendix J.

Referring to Appendix J, it can be found that each vehicle in the consist has the following data:

- Position in the train
- Length
- Weight (empty + load)
- Type of brakes valves (AB, ABD, or ABDW)
- Bearing types

5.6. Difficult Train Handling Scenario

The difficult train handling scenario to be implemented will use continuous film footage for the visual, and use the adjusted track geometry data base to allow the development of a replica of the terrain found at the Crestview, FL accident site.

The train handling scenario will start at milepost 337 (film frame #96497) and end at milepost 342 + 4980 ft (film frame #114694).

Prior to the on-line motion picture projector reaching film frame #114694, the off-line projector will be rewound and positioned to film frame 3. Both projectors have mounted on them identical core films. The on-line projector will be near the end of its film and the off-line projector will be at the beginning of its film.

When the on-line projector reaches film frame #114694 it will be turned off and rewound, and the off-line projector will be turned on. There will be a flicker on the motion picture screen due to the mismatch of background scenery as the two projectors are exchanged.

The track geometry data base for the two core films, mounted on both projectors, must always be in synchronism with their respective film positions (frame numbers). The track geometry data bases for each core film are identical. The only exception will be when the alternate event has been selected. When this is to occur, approximately 7 miles of grade data are removed from the core film data base and replaced by the grade data base developed for the difficult train handling scenario (see Appendix K).

Track geometry data bases for the end and beginning of the core films, film frame numbers 114694 and 3, respectively, must be continuous to avoid transient conditions in the simulation program as the projectors are exchanged.

The track geometry data bases are continuous for both the beginning and end of the core film except for elevation. The correction for the difference in elevation will be made in software. The correction is to take the final elevation (frame #114694) minus the initial elevation (frame 3) and add this value to all elevation stations. The constant (K) for a core film repeat will be:

$$\begin{aligned} K &= 180.84 \text{ (frame #114694 core film)} \\ &- 210.8 \text{ (frame 3 core film)} = -29.96 \text{ feet} \end{aligned}$$

The value of -29.96 must be added to frame 3 and all subsequent elevation data. The constant (K) for a core film repeat after the difficult train handling scenario is used is:

$$K = 222.35 \text{ (frame #114694)} - 210.8 \text{ (frame 3)} = +11.35 \text{ feet}$$

When the difficult train handling scenario is to be implemented, the core film grade data must be exchanged with the difficult train handling grade data base. The instructor for the Evaluator must make the decision to use the new data prior to film frame #96497. If the decision is not to use it, nothing has

to be done. When the decision is to use it, then the new grade data base must be exchanged with the core film data base at frame #96497. The difficult train handling grade data base is tabulated in Appendix K.

Speed boards shown on the film are properly sequenced to regulate train speeds to 25 mph prior to entering the pseudo Crestview scenario. This is the desired speed for the train between mileposts 337 and 342.

A train order is necessary, and must be issued to engineer trainees using the Evaluator for speed restriction not to exceed 25 mph between mileposts 339 and 342. This train order is required because there are multiple speed boards within this trackage that display speed limits greater than 25 mph. Speed board locations and their respective speed limits are tabulated in Appendix J.

Appendix J details the physical data on locomotives and each trailing vehicle that was in the consist for the Crestview, FL accident.

APPENDIX J
CRESTVIEW DATA TRAIN MAKEUP AND GRADE DATA

SPECIFICATIONS ON THE LOCOMOTIVES

The locomotive consist was comprised of five diesel-electric 4-axle units as follows:

<u>Init. &</u>			<u>Manufacturer</u>	<u>H.P.</u>	<u>Gross Wt.</u>	<u>Brake Schedule</u>
L&N	1045	GP-30	Electromotive Division	2250	250,000 lb	26-L
L&N	1013	GP-30	Electromotive Division	2250	250,000 lb	26-L
SCL	515	GP-38-2	Electromotive Division	2000	265,000 lb	26-L
L&N	510	GP-9	Electromotive Division	1750	248,650 lb	24-RL
L&N	4129	GP-38-2	Electromotive Division	2000	256,000 lb	26-L
